ANGELES LINK PHASE 1

GREENHOUSE GAS (GHG) EMISSIONS EVALUATION

FINAL REPORT – DECEMBER 2024

SoCalGas commissioned this GHG Emissions Evaluation from Stantec Consulting Services Inc. The analysis was conducted, and this report was prepared, collaboratively.

Table of Contents

1 Executive Summary 1.1
2 Study Approach 2.1
3 Technical Approach 3.1
3.1 Set Up Implementation Scenarios 3.1
3.2 Identify Emissions Source Types 3.1
3.2.1 Hydrogen Production (Third-Party) 3.2
3.2.2 Hydrogen Storage (Third-Party) and Transmission 3.3
3.2.3 Hydrogen Industrial End Users 3.3
3.2.4 Opportunities to Minimize GHG Emissions 3.3
3.3 Formation of GHG 3.4
3.4 GHG Emission Factors 3.5
3.4.1 Combustion of Displaced Fossil Fuels 3.5
3.4.2 Combustion of Hydrogen 3.6
3.5 Calculation Methodology 3.7
3.5.1 Infrastructure 3.7
3.5.2 End Users 3.7
3.5.3 Conduct Emissions Calculations 3.13
4 Background Information 4.1

1 EXECUTIVE SUMMARY

Southern California Gas Company (SoCalGas) is proposing to develop a clean renewable hydrogen[1] pipeline system to facilitate transportation of clean renewable hydrogen from multiple regional third-party production sources and storage sites to various delivery points and end users in Central and Southern California, including in the Los Angeles Basin. The CPUC's Phase 1 Decision,[2] approving the Memorandum Account for SoCalGas's proposed Angeles Link, allows SoCalGas to track costs for conducting the feasibility studies. In the Decision, the CPUC defines clean renewable hydrogen as hydrogen that does not exceed 4 kilograms of carbon dioxide equivalent (CO_2e) on a lifecycle basis per kilogram of hydrogen produced and does not use fossil fuel[3] in the hydrogen production process.

This greenhouse gas (GHG) study (GHG Study or Study) is one of the studies established to answer questions raised by the CPUC and other parties to the proceeding. The Decision directs (OP 6 (n)) SoCalGas to provide the findings demonstrating compliance with environmental laws and public policies. To demonstrate how clean renewable hydrogen could support environmental laws and public policies, this Study conducts an initial evaluation of projected GHG emissions from hydrogen infrastructure including those attributable to third-party production and third-party storage; and of anticipated GHG emission reductions from end-users; and overall GHG benefits associated with Angeles Link. This feasibility study is based on information currently available, and the analysis and corresponding conclusions are expected to evolve over time.

This GHG Study evaluates direct GHG emissions4 associated with hydrogen combustion associated with new infrastructure (i.e., third-party production, third-party storage, and

---

[1] In the California Public Utilities Commission (CPUC)'s Angeles Link Phase 1 Decision 22-12-055 (Phase 1 Decision), clean renewable hydrogen refers to hydrogen that does not exceed 4 kilograms of carbon dioxide equivalent (CO2e) produced on a lifecycle basis per kilogram of hydrogen produced and does not use fossil fuels in the hydrogen production process.

[2] California Public Utilities Commission (CPUC), 2022, Adopted Decision 22-12-055 - Decision Approving the Angeles Link Memorandum Account to Record Phase One Costs, December 15, https://docs.cpuc.ca.gov/PublishedDocs/Published/G000/M500/K167/500167327.PDF

[3] Fossil fuel is defined as a mixture of hydrocarbons including coal, petroleum, or natural gas, occurring in and extracted from underground deposits.

[4] In this Study, direct GHG emissions refer to GHG emissions from combustion, and indirect GHG emissions refer to GHG associated with non-renewable grid electricity or the estimated effect of potential hydrogen leakage on greenhouse gases in the atmosphere.

transmission of hydrogen),[5] as well as GHG emissions reductions associated with displaced fossil fuels by end users in the mobility, power generation, and hard-to-electrify industrial sectors.[6] Indirect GHGs from electricity are zero since it was assumed that only renewable electricity could be used to produce hydrogen that complies with CPUC's definition of clean renewable hydrogen. Should the need arise for the use of non-renewable grid electricity to produce hydrogen, the associated GHG emissions associated with production would include non-zero indirect GHGs. The GHG emissions associated with water procurement, water conveyance, and water treatment for production of hydrogen were not included in the scope of this Study.[7] Similarly, GHG emissions associated with transportation of other materials such as biomass to the production site or biomass feed preparation are beyond the scope of this feasibility study.

SoCalGas will not be producing clean renewable hydrogen as part of Angeles Link, and it is anticipated that third-party producers would complete thorough environmental review of their projects when proposed pursuant to the California Environmental Quality Act (CEQA) and the National Environmental Policy Act (NEPA), as applicable, and that review would evaluate the potential GHG emissions associated with that production.

Projected quantities of displacement of diesel and gasoline by hydrogen fuel cells in the mobility sector; and anticipated replacement of natural gas with hydrogen in the power generation and hard-to-electrify industrial sectors were based on estimated demand values provided by the parallel Demand Study.

The potential climate considerations of hydrogen leakage, the potential for which was evaluated in the parallel Leakage Study Report, for both general hydrogen infrastructure and Angeles Link infrastructure, are also discussed. Specifically, a preliminary high-level estimate of the impacts to predicted overall (end user reductions minus infrastructure emissions) GHG reductions (using GWP 100) was conducted. Additionally, a summary of the range of estimated global warming potentials (GWP) of hydrogen found in the literature is provided for both the 20 and 100 year time horizons, that would be considered

[5] The terms "new infrastructure" and "hydrogen infrastructure" refer to general hydrogen infrastructure comprised of third-party production, third-party storage, and transmission. The term "Angeles Link infrastructure" refers to transmission via pipelines including compression which supports both storage and transmission of hydrogen.

[6] Mobility, power generation, and hard-to-electrify industrial sectors as defined in the parallel Demand Study.

[7] The GHG emissions associated with water conveyance for production of hydrogen were also outside the scope of the parallel Angeles Link Phase 1 Water Resources Evaluation due to the variety of potential water supply sources and unknown final selection of sources third-party producers may pursue to produce clean renewable hydrogen. In response to stakeholder feedback on potential GHG emissions associated with water supply development, the Water Resources Evaluation added a supplemental desktop analysis of potential GHG emissions associated with water supply treatment and conveyance and that analysis is now included as part of that separate study.

for hydrogen as an indirect GHG.[8] Evaluation of methane leakage in the hydrogen industry is outside the scope of this feasibility analysis.

The Demand Study, which was relied upon when estimating initial projected GHG emissions, projected economy wide demand by 2045 in SoCalGas's service territory using three scenarios: conservative demand, moderate demand, and ambitious demand. In comparison to the Demand Study values noted above, the projected throughput of Angeles Link, which is expected to support a portion of that demand, is estimated to range from approximately 0.5 to 1.5 million metric tonnes per year (MMTPY). The low, medium, and high throughput scenarios for the Angeles Link buildout (0.5 MMTPY, 1.0 MMTPY, and 1.5 MMTPY) align with the conservative, moderate, and ambitious demand scenarios (1.9 MMTPY, 3.2 MMTPY, and 5.9 MMTPY)

To estimate potential GHG emissions associated with the Project, including those from third-party production and storage and end users, GHG estimates were calculated using initial estimates from the Demand Study. Then the ratio of anticipated hydrogen throughput values for Angeles Link to the projected values in the Demand Study were calculated for each of the conservative (26.85%), moderate (31.12%), and ambitious (25.36%) scenarios. The ratios were applied to the GHG estimated emissions using the Demand Study Scenarios to estimate potential GHG emission reductions associated with Angeles Link Throughput Scenarios. This analysis is shown in Table ES-1 below.

Table ES-1
Direct GHG Reduction Estimates for Demand Study Scenarios Applied to Projected Angeles Link Throughput Scenarios

Scenario	Total Projected Hydrogen Demand (MMTPY)	Overall GHG Reductions for Demand in 2045 (MMTPY)	Angeles Link Projected Hydrogen Throughput (MMTPY)	Overall GHG Reductions for Angeles Link Throughput in 2045 (MMTPY)
Low	1.9	16.7	0.5	4.5
Medium	3.2	24.9	1	7.8
High	5.9	35.7	1.5	9.0

[8] The estimated effect of potential hydrogen leakage as an indirect GHG is discussed in Section 9 of this document.

Key Findings: Demand Scenarios

The key findings for GHG emission reductions based on the Demand Study Scenarios are as follows and are discussed further herein.

- Projected up to nearly 17 and 36 million metric tons of CO_2e per year removed from SoCalGas geographic service territory by end users by 2045 in conservative and ambitious demand scenarios of the Demand Study, respectively. The reductions are equivalent to the annual GHG emissions of approximately 45 and 96 natural gas fueled power plants, respectively per EPA Calculator.
  - Mobility sector comprises 72.5% and 50.3% of overall GHG reductions based on the conservative and ambitious demand scenarios, respectively. The GHG reductions estimated for the conservative and ambitious demand scenarios in 2045 are equivalent to removing approximately 2.7 million and 4.3 million gasoline passenger vehicles off the roads per year, respectively.
  - Power generation and hard to electrify industrial sectors comprise 41.7% and 8.1% of the overall GHG reductions, respectively, based on the ambitious demand scenario.
  - Power generation and hard to electrify industrial sectors comprise 23.6% and 3.9% of overall GHG reductions, respectively, based on the conservative demand scenario.
  - Infrastructure GHG emissions are projected to be negligible when compared to overall emission reductions, at 0.29% and 0.25% of end-user reductions for conservative and ambitious demand scenarios, respectively.

Key Findings: Angeles Link Throughput Scenarios

The key findings for GHG emission reductions for Angeles Link Throughput Scenarios, which accounts for emissions from not just transmission of hydrogen, but also from third-party production and storage as well as end users, are as follows and are discussed further herein.

- Projected about 4.5 and 9 MMT of CO2e per year removed from SoCalGas's geographic territory by end users by 2045 in Angeles Link Low and High Throughput Scenarios, respectively.
- Mobility sector comprises 72.5% and 50.3% of overall GHG reductions based on the Angeles Link Low and High Throughput value scenarios, respectively. The GHG reductions estimated for the Low and High Throughput Scenarios in 2045 are equivalent to 725,000 and more than 1 million gasoline passenger vehicles driven for one year, respectively.[9]

[9] EPA, 2023a, Greenhouse Gas Equivalencies Calculator, https://www.epa.gov/energy/greenhouse-gas-equivalencies-calculator#results

- Power generation and hard to electrify industrial sectors comprise 41.7% and 8.1% of overall GHG emission reductions, respectively, based on the High Throughput Scenario.
- Power generation and hard to electrify industrial sectors comprise 23.6% and 3.9% of overall GHG emission reductions, respectively, based on the Low Throughput Scenario.
- Infrastructure GHG emissions are projected to be negligible when compared to overall emission reductions at 0.29% and 0.25% of end-user reductions for Low and High Throughput Scenarios, respectively.

Additional details related to both the Demand Scenarios and Angeles Link Throughput Scenarios are provided below.

2030 Ambitious Demand Scenario: In 2030, the Ambitious Demand Scenario predicts a reduction of about 6 MMTPY of CO_2e due to hydrogen replacing fossil fuels. This reduction includes the emissions from producing, storing, and transmitting hydrogen. This amount of reduction is comparable to the energy use of about 740,000 homes for one year, according to the EPA's GHG calculator.[10] In terms of specific contributions, Angeles Link is expected to meet about 25% of the projected hydrogen demand identified in the Demand Study. This means that the specific GHG reductions attributed to Angeles Link under the High Throughput Scenario are estimated at about 1.45 million MT CO_2e per year, which is equivalent to the energy use of approximately 189,000 homes for one year.

2045 Ambitious Demand Scenario: In 2045, the scenario estimates an overall reduction in CO_2e emissions of about 36 MMTPY, again due to the displacement of fossil fuels by hydrogen. These reductions are equivalent to the annual electricity usage of over 4.6 million homes, as per the EPA's calculator. Angeles Link is expected to supply the same percentage (about 25%) of the total hydrogen demand in SoCalGas service territory, as projected in the Ambitious Demand Scenario. As a result, the GHG emissions reductions specifically associated with Angeles Link in the High Throughput Scenario for 2045 are estimated at about 9.0 million MT CO_2e per year. This would correspond to the energy use of roughly 1.1 million homes for one year.

Mobility Sector: In the Mobility sector, the estimated CO_2e reductions under the Ambitious Demand Scenario are approximately 4.4 million MT in 2030 and about 18 million MT by 2045. The reductions by 2045 are equivalent to the emissions from around 4.3 million gasoline-powered passenger vehicles driven for a year. The sector accounts for between 50% to 83% of total GHG emissions reductions, varying by scenario and year. The largest contributors are heavy-duty vehicles (55.5% in 2030 and 62.8% in 2045), followed by buses (33.6% in 2030 and 22.0% in 2045), and medium-duty vehicles (7.3% in 2030 and 9.7% in 2045). Reductions from on-road vehicles outweigh those from off-road vehicles, mainly due to the higher displacement of fossil fuels. In the High

[10] EPA, 2023a, GHG Calculator, Ibid.

Throughput Scenario, the reductions for 2030 are about 1.1 million MT CO2e per year, increasing to about 4.6 million MT CO2e by 2045. The 2045 reductions would be equivalent to the emissions from 1 million gasoline-powered vehicles driven for a year.

Power Generation Sector: In the Power Generation sector, it's projected that by 2030, there could be a reduction of 0.16 million MT of CO2e under the Ambitious Demand Scenario, and by 2045, this could increase to about 15 million MT CO2e. Over 78% of these reductions are expected from the peaker and baseload plant sub-sectors in all years under this scenario with the remaining reductions attributable to the cogeneration sub-sector. By 2045, these reductions are equivalent to the yearly electricity consumption of approximately 1.9 million homes, according to the EPA's calculator. Under the High Throughput Scenario, the reductions are estimated at about 41,000 MT CO2e per year for 2030 and about 3.8 million MT CO2e per year by 2045. The reductions for 2045 under this scenario are comparable to the energy use of around 480,000 homes for one year.

Hard to Electrify Industrial Sectors: In the industrial sectors that are difficult to electrify, the estimated CO2e reductions under the Ambitious Demand Scenario are around 1.1 million MT in 2030 and could rise to about 2.9 million MT by 2045. The 2045 reductions would be equal to the annual electricity usage of about 365,000 homes. In this scenario, refineries are the largest contributors, accounting for 65.5% of reductions in 2030, followed by the Food and Beverage sector (13.4%), Stone, Glass, and Cement (12.1%), and Metals (5.3%). Please note that refineries are only considered in the Ambitious Demand Scenario and refineries comprise about one-quarter of the Demand in this scenario. These percentages remain consistent from 2030 to 2045. In the High Throughput Scenario, the reductions are estimated at about 290,000 MT CO2e per year for 2030 and about 730,000 MT CO2e per year by 2045. The 2045 reductions equate to the energy use of around 96,000 homes for one year.

Hydrogen Infrastructure Emissions: Emissions associated with new hydrogen infrastructure are evaluated. The results of the conservative estimate prepared represent a small fraction of the emissions reductions achieved by end-users adopting hydrogen in the study region.

Specifically, in the Ambitious Demand Scenario:

- By 2030, emissions from the new hydrogen infrastructure are estimated at about 16,600 MT of CO2e per year. This accounts for 0.29% of total CO2e reductions expected from end-users based on hydrogen usage projections.
- By 2045, these emissions increase to about 87,900 MT per year of CO2e, which constitutes 0.25% of the total CO2e reductions from end-users. This accounts for 0.25% of total CO2e reductions expected from end-users based on hydrogen usage projections.

For Angeles Link, under the High Throughput Scenario:

- In 2030, the estimated emissions attributed to the new infrastructure are estimated to be around 4,200 MT of CO2e per year. This accounts for 0.29% of total CO2e reductions expected from end-users based on hydrogen usage projections.
- By 2045, this figure is projected to rise to 22,300 MT of CO2e per year. This accounts for 0.25% of total CO2e reductions expected from end-users based on hydrogen usage projections.

Stakeholder Input

The input and feedback from stakeholders including the Planning Advisory Group (PAG) and Community Based Organization Stakeholder Group (CBOSG) has been helpful to the development of this Final GHG Study Report. For example, in response to stakeholder comments, the Study includes an estimate of the impact to estimated GHG reductions of a preliminary high-level volumetric estimate of the potential for leakage from hydrogen infrastructure from the Leakage Study Report, as well as presenting a summary of the estimated Global Warming Potential (GWP) 100 and GWP 20 for hydrogen available in the literature. In addition, the study includes a review of relevant literature provided by stakeholders, as applicable. The feedback that has been received related to this Study is provided in Section 11.

SoCalGas

GHG AND OTHER AIR EMISSIONS
DRAFT STUDY - ANGELES LINK

About the Research

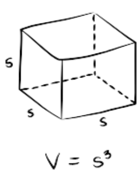
Understanding the Draft Study

Study Purpose

- Estimate GHG combustion emissions associated with Angeles Link infrastructure including third party production and third party storage.
- Assess projected GHG combustion emission reductions from displacing fossil fuels with hydrogen in various end user sectors.

Scope

- Focus on direct combustion GHG emissions from hydrogen infrastructure and reductions from fossil fuel displacement.
- Includes examination of indirect climate impacts for potential hydrogen leakage associated with infrastructure based on a summary of leakage rates provided in the Leakage Study.



Key Assumptions

- Use of renewable electricity for hydrogen production to ensure zero GHG emissions from the energy supply side.
- Anticipation of technological efficiencies and market adoption rates to project climate benefits.

Limitations

- Does not account for water conveyance and biomass transportation impacts and other potential contributors to full lifecycle GHG assessments.
- Acknowledges the draft nature of the study, indicating ongoing refinement of data and conclusions.

Informed by Research

- Literature and Studies: Equity Principles for Hydrogen, AC Transit, 2022. Bertagni et al., 2022, CARB 2022; Ocko, I. and S. Hamburg, 2023; Paulot, F., et al., 2021; Sand, M., et al., 2023, Sun, Tianyi, et al., 2024
- Notable references include detailed discussions on the impact of hydrogen leakage on overall GHG reductions and climate impacts.

Understanding the Impact of Angeles Link

Identifying End-Users Served by Angeles Link

Mobility Sector

- Heavy-Duty Trucks, Medium-Duty Vehicles, Buses, Agriculture, Construction & Mining Equipment, Cargo Handling Equipment, Ground Support Equipment, Commercial Harbor Craft.

Power Generation Sector

- Turbines and Co-generation.

Hard-to-Electrify Industries

- Chemical Manufacturing, Metal Refining and Treatment, Stone/Glass/Cement, Food & Beverage, Paper & Pulp, Aerospace, Refineries.

Overview of Direct GHG Reduction Estimates for Demand Study Scenarios Applied to Projected Angeles Link Throughput Scenarios

- **Demand Scenarios:** Specifies the level of market adoption (Low, Moderate, High) for hydrogen by end users.
- **Total Projected Hydrogen Demand:** This is how much hydrogen is expected to be used in each scenario.
- **Overall GHG Reductions based on Demand Scenarios in 2045:** This shows the estimated GHG reductions associated with Demand Scenarios.
- **Angeles Link Projected Hydrogen:** It reflects the specific contribution of Angeles Link within the larger market context.
- **Overall GHG Reductions based on Throughput Scenarios in 2045:** This represents the total anticipated GHG reduction in 2045, reflecting Angeles Link contribution.

DEMAND SCENARIO	TOTAL PROJECTED HYDROGEN DEMAND (MMT/YR)	OVERALL GHG REDUCTIONS BASED ON DEMAND SCENARIOS IN 2045	ANGELES LINK PROJECTED HYDROGEN (MMT/YR)	OVERALL GHG REDUCTIONS FOR ANGELES LINK THROUGHPUT IN 2045
CONSERVATIVE	1.9 MMT/yr Least amount of hydrogen expected to be used.	16.7 MMT/yr Amount of GHG reduced if less hydrogen is used.	0.5 MMT/yr Amount of hydrogen Angeles Link would transport in this scenario.	4.5 MMT/yr GHG reduction directly from Angeles Link's operations.
MODERATE	3.2 MMT/yr A moderate amount of hydrogen expected to be used.	24.9 MMT/yr Amount of GHG reduced with moderate hydrogen use.	1.0 MMT/yr Hydrogen amount transported by Angeles Link in this scenario.	7.8 MMT/yr GHG reduction from Angeles Link, reflecting its impact.
AMBITIOUS	5.9 MMT/yr The highest amount of hydrogen expected to be used.	35.7 MMT/yr Maximum GHG reduction with high hydrogen use.	1.5 MMT/yr Most hydrogen transported by Angeles Link under this scenario.	9.0 MMT/yr Largest GHG reduction by Angeles Link, showing significant impact.

Visualizing the Impact: GHG Reductions Through Angeles Link

Understanding the Impact of Angeles Link on GHG Reduction over time

The visualization underscores a dramatic scale-up in the impact of GHG reductions enabled by Angeles Link, with energy savings equivalent to homes increasing nearly sixfold from 2030 to 2045, highlighting significant long-term environmental benefits.

1.4MMT

the equivalent of 180,000 homes

In 2030, Angeles Link would have reduced emissions by 1.4, the equivalent of 180,000 homes

9MMT

the equivalent of 1.1 million homes

Each icon represents the energy usage of 20,000 homes.

GHG Reduction by 2045 for Angeles Link Throughput

4.5 MMT of CO2 Equivalent:

83M

tree seedlings grown for 10 years.

7.8 MMT of CO2 Equivalent:

144M

tree seedlings grown for 10 years.

9 MMT of CO2 Equivalent:

166M

tree seedlings grown for 10 years.

- **Low Throughput:** Angeles Link transports **0.5 MMT/year** of clean hydrogen, helping reduce GHGs by **4.5 MMT/year**.
- **Moderate Throughput:** Angeles Link transports **1.0 MMT/year** of clean hydrogen, reducing GHGs by **7.8 MMT/ year**.
- **High Throughput:** Angeles Link transports **1.5 MMT/year** of clean hydrogen, reducing GHGs by **9.0 MMT/ year**.

Insights on Sector-Specific Impact based on Demand Scenarios

GHG Emission Reductions Across Sectors on Car Emissions Equivalent, by 2045

**Each icon represents 250,000 cars removed*

The Mobility Sector's reduction impact is roughly six times that of the Industrial Sectors and slightly higher than that of Power Generation, underscoring the critical role of transportation advancements in achieving broader emission reduction targets

18MMT/year

The Mobility Sector GHG reduction is equivalent to removing about **4.2 million cars.**

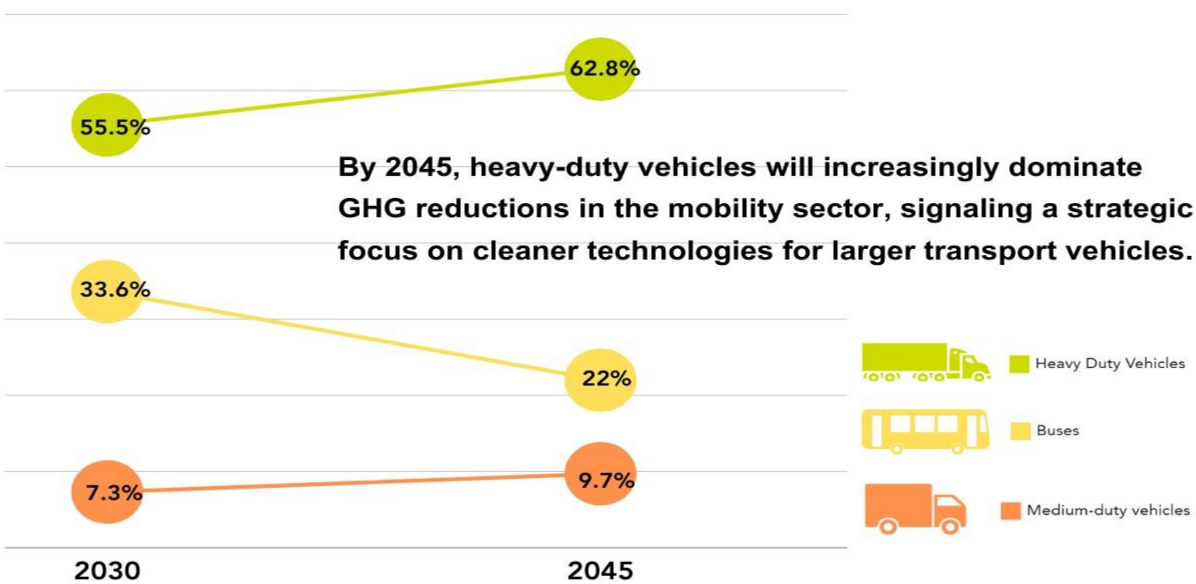
15MMT/year

The Power Generation Sector GHG reduction is equivalent to removing about **3.33 million cars.**

2.9MMT/year

Industrial Sectors GHG reduction are equivalent to removing about **644,000 cars.**

Trends in Mobility Subsector Contributions to GHG Reductions: 2030 vs. 2045

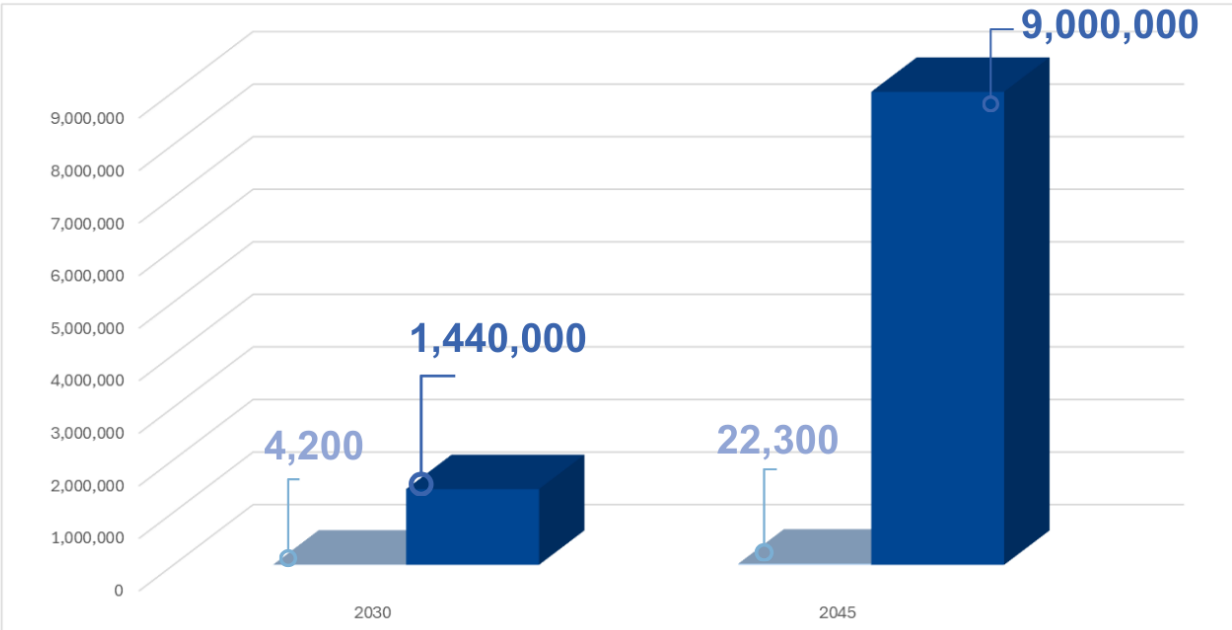


By 2045, heavy-duty vehicles will increasingly dominate GHG reductions in the mobility sector, signaling a strategic focus on cleaner technologies for larger transport vehicles.

Evaluating the Environmental Impact of the Angeles Link

New Hydrogen Infrastructure Emissions vs. End-Users Reductions: Angeles Link's Impact from 2030 to 2045

Estimated GHG Combustion Infrastructure Emissions vs. Expected GHG Combustion Reductions from End Users Served by Angeles Link (2030 & 2045)



Projected GHG Combustion Infrastructure Emissions (MT CO2e/yr)

Expected GHG Combustion End User Reductions (MT CO2e/yr)

Note: *The terms "new infrastructure" and "hydrogen infrastructure" refer to general hydrogen infrastructure comprised of third-party production, third-party storage, and transmission.*

Understanding the Impact of Hydrogen Leakage on Overall GHG reductions

3% Preliminary High-level Estimate of the Impact of Potential Leakage on Overall GHG reductions estimates is less than 3% for General Hydrogen Infrastructure.

1% Preliminary High-level Estimate of the Impact of Potential Leakage on Overall GHG reductions estimates is less than 1% for Projected Angeles Link Infrastructure.

2 STUDY APPROACH

The goals of this Study are to estimate GHG combustion emissions associated with the anticipated production, storage, and transmission of hydrogen and estimate GHG combustion emission reductions from end users of hydrogen in the mobility, power generation, and hard to electrify industrial sectors.[11] The parallel Demand Study provided initial details and scenarios that were used to complete these GHG emission estimates. Additional evaluation of GHG emissions for the estimated ranges of Angeles Link throughput of 0.5 to 1.5 MMT per year of hydrogen was also conducted.

The geographic region of this study includes highly populated areas and encompasses a wide range of industrial end-users with the potential to convert to hydrogen as a source of fuel. Among these potential end-users are the San Pedro Ports Complex comprised of the Port of Los Angeles and the Port of Long Beach, the most highly trafficked ports in the United States[12] and Los Angeles International Airport, one of the top five busiest airports in the world.[13] The study covers the time period from 2030 to 2045 consistent with the assumptions in the Demand Study.

Where applicable, the Study relies on specific technical information from regulatory agencies, transportation agencies, and equipment manufacturers. Research conducted by entities such as academic institutions was evaluated to determine the best available methods for quantifying emissions of GHG from the combustion of hydrogen. When specific information was not available, estimates were made based on availability of related data, or assumptions were developed.

For this Study, GHG emissions from combustion of fossil fuels (diesel, gasoline, and natural gas) are comprised of carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O); and GHG emissions from combustion of hydrogen include no carbon emissions and only trace amounts of N_2O.[14] Hydrogen considerations as an indirect GHG have be discussed in a number of research studies and although a single value or range has not been formally adopted by reporting agencies like the California Air Resources Board (CARB), the Environmental Protection Agency (EPA), or the IPCC, it's an important study consideration. The impact of hydrogen to climate change as discussed in the scientific

[11] Estimation of GHG emissions associated with project construction will be considered during the California Environmental Quality Act (CEQA) / National Environmental Policy Act (NEPA) process of the project.

[14] Some studies indicate that there is a possibility for N_2O to form directly from the interaction of N_2 and O_2 (primary components of air) during combustion of any fuel.

literature including estimates of effective GWPs for hydrogen are presented in this study report.

Technical Research

The Study collected, reviewed, and analyzed technical research studies and information related to GHG emissions associated with the combustion of hydrogen. This analysis included, but was not limited to:

- Available literature and studies from research-based academic institutions such as the University of California Irvine (UCI) Combustion Laboratory and the Georgia Institute of Technology and private organizations such as the Electric Power Research Institute (EPRI); and technical data or research identified by stakeholders (CBOSG and PAG members) including Environmental Defense Fund (EDF).
- Existing, proposed, and potential future regulatory requirements from federal agencies including the Environmental Protection Agency (EPA), the Department of Energy (DOE), state agencies such as the California Air Resources Board (CARB) and the California Energy Commission (CEC), and local agencies including the nine local air districts located within the geographic scope of this study such as South Coast AQMD and San Joaquin Valley Air Pollution Control District (APCD);
- Technical literature and data releases from government agencies and laboratories including the DOE and the National Renewable Energy Lab (NREL); and
- Potential GHG minimization opportunities from technological advancements.

3 TECHNICAL APPROACH

The following assessment process (Figure 1) was used for the technical approach of this Study. The approach was based on review of technical research studies, research of anticipated technological advancements, stakeholder input and review of the expected evolution of regulatory frameworks.

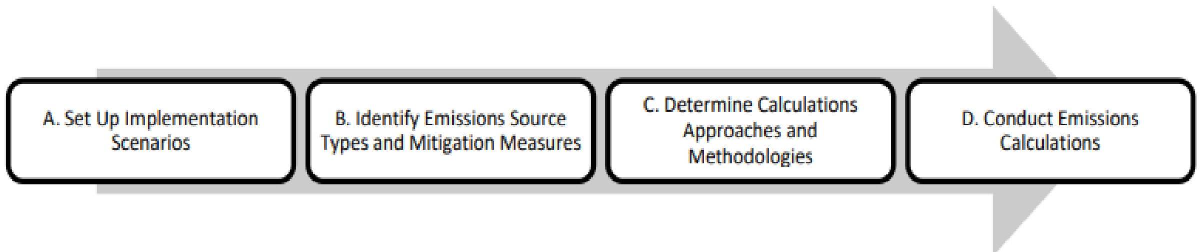

Figure 1. GHG Emissions Assessment Process for GHG Emissions Associated with Angeles Link

3.1 SET UP IMPLEMENTATION SCENARIOS

To evaluate potential GHG emissions and emissions changes associated with Angeles Link, including third-party production and storage, as well as end users, the timeframe from 2030 to 2045 was used. Consistent with the findings of the Demand Study, end use sectors are anticipated to achieve the ability to accommodate 100% hydrogen fuel use at different times due to availability of technology and feasibility of transitioning existing equipment and building new infrastructure. The use of clean renewable hydrogen as fuel for each end-use sector was evaluated beginning with 2030 based on data from the Demand Study. GHG emissions were calculated using the approaches described in the next steps for both the three hydrogen Demand Study scenarios – conservative (1.9 MMTPY), moderate (3.2 MMTPY), and ambitious (5.9 MMTPY), as well as the three hydrogen Angeles Link throughput scenarios – low (0.5 MMTPY), medium (1.0 MMTPY), and high (1.5 MMTPY).

3.2 IDENTIFY EMISSIONS SOURCE TYPES

The Study evaluated GHG combustion emissions by developing emission calculation approaches and methodologies for the following:

- Infrastructure (Third-Party Production, Third-Party Storage, and Transmission)
- End Users (Mobility, Power Generation, and Hard to Electrify Industrial)

Evaluation of GHG emission minimization opportunities was focused on equipment efficiency to minimize fuel use and thereby minimize GHG, as well as equipment design that minimizes formation of N_2O.

The study acknowledges that certain technical literature identified the potential for hydrogen leakage in the production, storage, and transmission of hydrogen. This potential, as well as opportunities to minimize and mitigate the potential for leakage, are discussed in the parallel Final Leakage Study Report. Evaluation of methane leakage in the hydrogen industry is outside the scope of this feasibility analysis.

3.2.1 Hydrogen Production (Third-Party)

Three potential clean renewable hydrogen production methods were evaluated as shown below. Each are projected to produce clean renewable hydrogen consistent with the clean renewable hydrogen definition in the CPUC's Phase 1 Decision. Further details regarding production methodologies are available in the parallel Phase 1 Production Study. Appendix A provides details regarding the development of GHG emission factors related to production. Appendix B includes a summary of the anticipated carbon intensities of production options as discussed in the literature.

1) Electrolyzers[15] powered by renewable electricity split water molecules into oxygen (O_2) and hydrogen (H_2). This process does not use combustion so there is no potential for GHG emissions from electrolyzers. It was assumed that only renewable electricity would be used and the indirect GHG emissions would be zero.
2) Biomass gasification[16] is a process that involves heat, steam, and oxygen to convert biomass to hydrogen without combustion.. It was assumed that only renewable electricity would be used and the process would be carbon neutral and therefore GHG emissions would be zero.
3) Renewable natural gas (RNG) fueled steam methane reformers (SMR). Steam methane reforming is a process in which biogas (RNG) reacts with steam in the presence of a catalyst to produce hydrogen and carbon dioxide. It was assumed that hydrogen would be used as the fuel for any combustion units, such as the heater. This method has direct GHG emissions and those potential emissions were evaluated. It was assumed that only renewable electricity would be used and the indirect GHG emissions would be zero.

The GHG estimates in this Final GHG Study Report related to anticipated third-party production options are based on combustion of 100% clean renewable hydrogen and use of renewable electricity. GHG emissions associated with water procurement, water conveyance, water treatment, and transport of feedstock such as biomass was out of scope for this Study. Estimated carbon intensity values for cradle-to-gate summarized from the literature are provided in Appendix B. Third-party producers will select the source and type of biomass that may be used during biomass gasification which will impact the carbon intensity of the biomass. The biomass used may affect the eligibility of whether

[15] DOE, 2024a, Hydrogen Production: Electrolysis, https://www.energy.gov/eere/fuelcells/hydrogen-production-electrolysis
[16] DOE, 2024b, Hydrogen Production: Biomass Gasification, https://www.energy.gov/eere/fuelcells/hydrogen-production-biomass-gasification

the hydrogen produced may be transported via Angeles Link pipeline depending on CPUC directives. Please refer to the Water Study and Production Study for additional information regarding the third-party production methodologies.

3.2.2 Hydrogen Storage (Third-Party) and Transmission

For the purpose of this Study, hydrogen storage may occur aboveground or underground, and will be delivered to end users via pipelines. Storage and transmission of hydrogen will require the use of compressors. Reciprocating or centrifugal compressors would be fueled by clean renewable hydrogen and would not produce CO_2. However, trace amounts of N_2O could form from the nitrogen present in the combustion air at specific temperatures. It was assumed that only renewable electricity would be used and the indirect GHG emissions would be zero. Electric driven compressors would be powered by renewable electricity and both direct and indirect GHG emissions would be zero.

3.2.3 Hydrogen Industrial End Users

Potential GHG emissions reductions from end users in three key sectors were evaluated: Mobility, Power Generation, and Hard to Electrify Industrial sectors. Information obtained from the parallel Demand Study informed the analysis of end uses in each of these three sectors, as well as their respective subsectors and are noted below:

- **Mobility:** sub-sectors include heavy-duty trucks, medium-duty vehicles, buses, agriculture, construction & mining, cargo handling equipment, ground support equipment, and commercial harbor craft.
- **Power Generation:** turbines are the primary source for potential GHG emissions in power generation.
- **Hard to electrify industrial:** subsectors include energy intensive industries such as refining, food and beverage manufacturing, primary and fabricated metals, stone, glass, and cement, paper, chemical manufacturing, and aerospace and defense.

Equipment types with the potential for GHG emissions across the power generation and industrial sectors include hot water boilers, steam generating units, process heaters, furnaces/kilns, internal combustion engines, turbines, and miscellaneous combustion equipment.

3.2.4 Opportunities to Minimize GHG Emissions

Opportunities to minimize GHG emissions are related to production methodologies and equipment used to combust hydrogen such as reciprocating or centrifugal compressors. Advanced production technologies, including electrolysis, biomass gasification and renewable natural gas-fueled steam methane reformers, provide opportunities to minimize GHG compared to traditional hydrogen production methods. Optimization of hydrogen storage and transmission includes implementing high-efficiency compressors powered by renewable electricity or hydrogen and ensuring robust infrastructure design to minimize hydrogen leakage. Various opportunities exist to minimize N_2O emissions, particularly during the design phase of combustion equipment.

3.3 FORMATION OF GHG

Greenhouse gases are a natural part of the Earth's atmosphere that keeps the earth's global mean temperature comfortable for and inhabitable by humans. Without greenhouse gases, the Earth would be much colder. While some atmospheric greenhouse gases are critical for the existence of life as we know it, an excess of greenhouse gases in the atmosphere has the potential to increase the greenhouse effect to a point where the increase in global mean temperature may disrupt global ocean currents, global wind patterns, expected climatic variations, and ultimately, the way life functions on Earth. It is important to understand which gases act as greenhouse gases in the atmosphere and what anthropogenic causes contribute to their release.

Human activities are responsible for increases in greenhouse gases in the atmosphere over the last 150 years. Combustion of fossil fuels occurs when the fuel is burned with oxygen, which can lead to the formation of CO_2 and water vapor (H_2O). CO_2 is one of the most prevalent anthropogenic greenhouse gases. Roughly half of Earth's greenhouse effect is attributable to water vapor in the atmosphere.[17] Increasing global mean temperatures increase the heat flux off the ocean and other bodies of water, which increases evaporation. As temperatures increase, the air in the atmosphere can hold more water due to decreased condensation and precipitation. Water vapor is a direct greenhouse gas, which absorbs the radiation from the Earth and reflects it back. Water vapor exacerbates the warming from other greenhouse gases. The primary difference between water vapor and the other GHGs is that it is condensable. The water cycle works to keep molecules of water in the atmosphere for only a small length of time, roughly nine days on average.[18] This is in comparison to carbon dioxide which can stay in the atmosphere for hundreds of years.

The concept of "global warming potential" (GWP) measures a greenhouse gas's (GHG's) ability to trap heat in the atmosphere compared to carbon dioxide (CO_2). Defined by the US Environmental Protection Agency (EPA)[19], GWP quantifies the heat a greenhouse gas can absorb over a specified period, using the impact of one ton of CO_2 as the reference. This metric is developed and regularly updated by experts at organizations like the Intergovernmental Panel on Climate Change (IPCC) based on comprehensive

---

[17] Buis, A., 2022, Steamy Relationships: How Atmospheric Water Vapor Amplifies Earth's Greenhouse Effect, NASA Climate webpage article, February 8, https://climate.nasa.gov/explore/ask-nasa-climate/3143/steamy-relationships-how-atmospheric-water-vapor-amplifies-earths-greenhouse-effect/

[19] EPA, 2024a, Greenhouse Gas Emissions: Understanding Global Warming Potentials, https://www.epa.gov/ghgemissions/understanding-global-warming-potentials

reviews of scientific studies. The updates incorporate the latest data, and the GWP values are assessed over different time spans — 20, 100, or 500 years[20]. The IPCC's Fifth Assessment Report (AR5)[21] recognized the 100-year GWP as a standard metric from the United Nations Framework Convention on Climate Change (UNFCCC), which was initially applied in the 1997 Kyoto Protocol. AR5 also noted that GWPs for gases that stay in the atmosphere for shorter periods have greater uncertainties compared to those that remain for several decades or centuries. The Sixth Assessment Report (AR6) was selected as the source for GWP values for carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O), as these were the most recently published GWPs.[22] The AR6 GWP values are used in this study since they are the most recent values. Reporting of GHG to CARB and EPA uses the AR4 GWP 100 value that is lower for methane (25 rather than 29.8). The Study anticipates that GWP for hydrogen will be evaluated for reporting purposes in the future and undergo an evolution in values similar to methane.

3.4 GHG EMISSION FACTORS

The Study evaluated direct GHG emissions from combustion of fossil fuels, hydrogen, and natural gas/hydrogen fuel blends.

3.4.1 Combustion of Displaced Fossil Fuels

Direct GHG emissions comprised of CO_2, CH_4, and N_2O were evaluated for combustion of displaced fossil fuels: natural gas, diesel, and gasoline. EPA Title 40 Code of Federal Regulations (CFR) Part 98 "Mandatory Greenhouse Gas Reporting," was selected as the source for fuel based GHG emissions factors for CO_2, CH_4, and N_2O in units of kilograms (kg) per million British Thermal Units (MMBtu). The GHG emissions factors for CO_2, CH_4, and N_2O associated with diesel, gasoline, and natural gas per EPA 40 CFR Part 98, as well as the GWP 20 and GWP 100 values from IPCC AR6 Table 7.15 of "Climate Change 2021 The Physical Science Basis" Working Group 1 Contribution to the Sixth Assessment Report of the Intergovernmental Panel on Climate Change,[23] are shown in Table 1 below.[24]

[20] IPCC, 2014 AR5 Synthesis Report: Climate Change 2014, https://www.ipcc.ch/report/ar5/syr/

[23] IPCC, 2021, Ibid.

[24] The AR6 GWP values are used in this study since they are the most recent values. Reporting of GHG to CARB and EPA currently uses the AR4 GWP 100 value that is lower for methane (25 rather than 27.0 – 29.8).

Table 1 Summary of Fossil Fuel GHG Combustion Emission Factors			
Pollutant	**CO_2 E.F. (kg/MMBtu)**	**CH_4 E.F. (kg/MMBtu)**	**N_2O E.F. (kg/MMBtu)**
Diesel	73.96	3.0 x 10-3	6.0 x 10-4
Gasoline	70.22	3.0 x 10-3	6.0 x 10-4
Natural Gas	53.06	1.0 x 10-3	1.0 x 10-4
GWP 100	1	29.8	273
GWP 20	1	82.5	273

3.4.2 Combustion of Hydrogen

This Study also explored whether greenhouse gases are produced when hydrogen is combusted. Pure hydrogen fuel does not contain carbon and is therefore considered an option for decarbonizing certain emissions sources and sectors where other low-carbon options might not be technically or economically feasible.[25] Nevertheless, minute amounts of CO_2 might still be detected when measuring emissions, but this CO_2 originates from the combustion air itself, which contains about 0.04% CO_2 by volume.[26] This CO_2 is not produced by the combustion process; instead, it remains unchanged and can exit through the exhaust stack. When combusting hydrogen small amounts of N_2O could potentially form from the interaction of N_2 and O_2 during combustion due to nitrogen and oxygen present in the combustion air. The possibility of forming N_2O is considered minimal and is most likely to occur at low combustion temperatures.[27] When hydrogen is combusted in combination with natural gas, the emissions include CO_2, methane (CH_4) which is unburned fuel from the natural gas component, and N_2O.

CO_2 emissions decrease as the percent of hydrogen in the fuel (on a volume basis) is increased, but they do not decrease linearly. As outlined in a paper published by the EPA titled, "*Hydrogen in Combustion Turbine Electric Generating Units Technical Support Document*," the difference in volume energy densities between natural gas and hydrogen

[26] West, J., 2019, Wait the Atmosphere is only 0.04% Carbon Dioxide. How Does it Affect Earth's Climate?, SciTechDaily, https://scitechdaily.com/wait-the-atmosphere-is-only-0-04-carbon-dioxide-how-does-it-affect-earths-climate/
[27] Colorado, A., V. McDonell and S. Samuelsen, 2017, Direct Emissions of Nitrous Oxide from Combustion of Gaseous Fuels, International Journal of Hydrogen Energy 42(1): 711-719, https://doi.org/10.1016/j.ijhydene.2016.09.202

causes a smaller CO_2 emissions reduction than the percentage of hydrogen in the fuel mixture by volume. However, the study also assessed the extent of N_2O emissions that can be expected from the combustion of hydrogen.

N_2O is a greenhouse gas that can be formed during combustion that has a 100-year GWP of 273 according to the EPA. N_2O accounts for a very small percentage of GHG combustion emissions from natural gas, gasoline, and diesel fuels, and very small percentage of the resultant CO_2e emissions. N_2O emissions can potentially form from nitrogen in a fuel or nitrogen in combustion air. Given the potential for N_2O formation from combustion air, the potential for N_2O emissions to occur as a result of hydrogen combustion was evaluated as part of this study. Based on research, an extremely conservative emission factor for N_2O of 2 ppmvd was used for this study. Details regarding development of the N_2O emission factor used in this Study report are provided in Appendix A.

3.5 CALCULATION METHODOLOGY

3.5.1 Infrastructure

GHG combustion emissions associated with hydrogen infrastructure, including third-party production and storage were estimated. For hydrogen production, GHG combustion emissions associated with production (i.e., steam-methane reforming) and compression for storage and transmission fueled by hydrogen were estimated. Preliminary assumptions were made to develop GHG combustion emissions estimates. The formula used to calculate these emissions is:

*Fuel Throughput x Emissions Factor * GWP = GHG Emissions (equation 1)*

The first equation (equation 1) multiplies the quantity of clean renewable hydrogen by the N_2O emission factor assumed in this Study for hydrogen. The emissions for N_2O are then multiplied by the GWP as shown in Table 1 to determine GHG emissions in units of CO2e.

This approach applies emission factors for direct GHG components from the combustion process, scaled according to the specific equipment and operations involved in hydrogen infrastructure.

3.5.2 End Users

Estimating the potential for hydrogen leakage associated with end users of Angeles Link was not feasible given the limited amount of information available. However, some limited information found in the literature has been added to Section 4.1.1 of the Leakage Study. This information was related to end users that may or may not be applicable to Angeles Link.

For end users, based on the emission source type identified, GHG emissions were estimated for combustion of the displaced fossil fuel (diesel, gasoline, natural gas) and for hydrogen combustion, as applicable. For example, specific end user equipment and facility data was not available. Calculations to estimate emissions were prepared using the following two equations:

*Fuel Throughput x Emissions Factor * GWP = GHG Emissions (equation 1)*

GHG Emission Reductions = Fossil Fuel GHG Emissions – Hydrogen GHG Emissions (equation 2)

The first equation (equation 1) multiplies the quantity of fuel by the GHG emission factor specific to the fuel for each GHG pollutant. These pollutants are CO_2, CH_4, and N_2O for combustion of fossil fuels and N_2O for combustion of hydrogen. Each GHG has a specific fuel dependent emission factor and a unique GWP as shown in Table 1. The emissions for each of CO_2, CH_4, and N_2O are multiplied by their respective GWP and then summed to obtain the total GHG emissions in units of CO2e.

The second equation (equation 2) calculates the GHG emission reductions in CO2e by subtracting the GHG emissions for hydrogen (either for N_2O from combustion of hydrogen or zero for hydrogen fuel cells) from the GHG emissions for combustion of displaced fossil fuels. The GHG emissions for combustion of hydrogen and for combustion of fossil fuels are both derived from equation 1.

GHG emissions were calculated at the unit level and scaled based on activity data quantified using information from the Demand Study. Calculations were prepared for the conservative, moderate, and ambitious scenarios in the Demand Study for each year from 2030 to 2045. The Study evaluated the potential for GHG emissions based on the type of equipment and specific source categories from the Demand Study. This approach ensures that both the potential for GHG emissions and opportunities for reductions are comprehensively evaluated.

The GHG emissions factors for CO_2, CH_4, and N_2O associated with diesel, gasoline, and natural gas per EPA 40 CFR Part 98, as well as the GWP 20 and GWP 100 values from IPCC AR6, are shown in Table 1. For combustion of clean renewable hydrogen with GHG emissions comprised entirely of N_2O, since the GWP 20 and GWP 100 for N_2O are both 273, the expected impacts in both short term and long term should be similar. Once each calculation estimates for GHG combustion emissions were prepared for new infrastructure and end use sectors, these results were summed to develop an overall estimate using equation 3:

Overall GHG Reductions = End User GHG Reductions - Infrastructure GHG Increases (equation 3)

This structured approach ensures a rigorous and detailed analysis, accommodating the specificities of the GHG emissions associated with different stages of the hydrogen value chain.

3.5.2.1 Mobility Sector

Most on-road and off-road vehicles in the Mobility sector currently use various liquid and gaseous carbon-based fuels driving internal combustion engines. The CARB Emission Factor (EMFAC) model[28] was used to provide activity data and/or emissions factors for on-road and off-road mobile sources. The EMFAC model provides activity data such as vehicle miles traveled, vehicle category population counts, fuel consumption by vehicle category, and emissions data for most mobile vehicle types evaluated in this Study. The model contains sufficient data to estimate CO_2, CH_4, and N_2O emissions for on-road mobile sources, and CO_2 emissions for off-road mobile sources. Since the EMFAC model does not include CH_4 and N_2O emissions data for off-road mobile vehicles, additional research was completed to establish the most representative CH_4 and N_2O emissions factors for off-road mobile sources. The EPA Emission Factors for Greenhouse Gas Inventories document most recently modified on September 12, 2023, was selected. This Study consolidates these emissions factors from the Annex tables in the EPA (2022) Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2020.[29]

3.5.2.2 Power Generation Sector

The calculation approach for Power Generation to determine the change in emissions after hydrogen adoption consisted of taking the difference in GHG combustion emissions associated with fossil fuels and GHG combustion emissions associated with hydrogen. Stationary source fossil fuel consumption was represented as natural gas for consistency with the Demand Study. The fuel types considered for stationary calculations were pure hydrogen, pure natural gas, and hydrogen-natural gas blends of various percentages.

For the power generation sector, hydrogen usage is expected to begin with hydrogen/natural gas blends and begin to use 100% hydrogen fuel as the technology becomes available. Blended fuels will continue to be used while the in-use units age out. The transition from blended fuels to 100% pure hydrogen fuels was evaluated by the Demand Study in the Power Generation model and was based on technological and economic feasibility and regulatory requirements. These blending assumptions from the Demand Study were utilized within this study.

Mitsubishi, Siemens, and GE are the three largest global turbine manufacturers and have each outlined plans for establishing pure hydrogen firing turbine technology for power

[28] CARB, 2024a, EMFAC, https://ww2.arb.ca.gov/our-work/programs/msei/on-road-emfac

[29] EPA, 2023c, Inventory of U.S. Greenhouse Gas Emissions and Sinks 1990-2021, EPA 430-R-23-002, April 13, https://www.epa.gov/system/files/documents/2023-04/US-GHG-Inventory-2023-Main-Text.pdf

generation. Siemens and GE have published goals to develop heavy-duty DLE and DLN turbines with the ability to combust pure hydrogen by 2030, and Mitsubishi set a goal to develop DLN turbines with the ability to combust 100% hydrogen fuel by 2025.[30]

While not specifically included in the blending assumptions, hydrogen fuel cell technology has also been proven useful in the Power Generation sector in such applications as primary power, back-up power, peak-shaving, grid stabilization, and tri-generation (power, heat, and hydrogen).[31]

3.5.2.3 Hard to Electrify Industrial Sectors

The calculation approach for Hard to Electrify Sectors to determine the change in emissions after hydrogen adoption consisted of taking the difference in GHG combustion emissions associated with fossil fuels and GHG combustion emissions associated with hydrogen. Stationary source fossil fuel consumption was represented as natural gas for consistency with the Demand Study. The fuel types considered for stationary calculations were pure hydrogen, pure natural gas, and hydrogen-natural gas blends of various percentages.

The Hard to Electrify Industrial sectors evaluated include energy intensive industries that currently uses mostly gaseous and liquid carbon-based fuels in internal and external combustion equipment. Although Angeles Link will deliver 100% hydrogen, usage in these sectors is anticipated to begin with hydrogen/natural gas blends in 2030 by the end users, behind the meter, and eventually transition to use 100% hydrogen fuel by 2050. Once pure hydrogen fuel combustion technology becomes available, it was assumed that blended fuel equipment would be retired or phased out until 100% of hydrogen demand would be utilized by equipment combusting pure hydrogen fuel in 2050. Equipment-level blended hydrogen combustion as a percentage of overall hydrogen consumption is depicted in Table 2B below.

Babcock and Wilcox offers a commercially available steam boiler that can operate on 100% hydrogen fuel, called BrightGen. This unit has the ability to switch between hydrogen and natural gas combustion as needed.[32] In 2020, AMF Bakery Systems released the Multibake VITA Tunnel Oven by AMF Den Boer which is fueled by pure

hydrogen. Hydrogen fueled ovens have the potential to help decarbonize the Food & Beverage Hard-to-Electrify Industrial sub-sector.[33]

The DOE is continuing to invest funding into the research and development of pure hydrogen capable combustion technologies to help decarbonize the Hard-to-Electrify Industrial sector. In January 2024, DOE announced $10.5M of funding into PACCAR Inc., Cummins Inc., and Powertrain for the development of heavy-duty hydrogen engine technology.[34]

Heavy-duty hydrogen turbine, engine, oven, and boiler technology has the strong potential to help decarbonize the Hard-to-Electrify Industrial sector. While not all of these technologies are commercially available yet, manufacturers have stated goals to produce this equipment within the next decade.

This Study does not dictate if end users will blend hydrogen with natural gas and makes assumptions regarding adoption rates based on currently available information regarding equipment and the anticipated evolution of adoption over time. Since only 100% clean renewable hydrogen will be delivered, to estimate GHG reductions at end users, assumptions regarding hydrogen adoption rates were made as shown in Tables 2A and 2B.

The values in Table 2A are based on an assumption of steady incremental increases with a goal of complete transition by 2050. The values in Table 2B were estimated based on manufacturer specification sheets and direct measurement studies. A dataset consisting of 22 data points, across 14 manufacturers, from manufacturers' data and scientific literature were used to estimate equipment-level hydrogen-natural gas blending percentages by taking a direct average. The estimated emissions are based on these assumptions.

3.5.3 Conduct Emissions Calculations

The Study prepared emission calculations using the emission factors and activity data compiled for each of the topic areas.

- The tool was designed to conduct calculations at the unit level (per unit equipment count, unit distance, unit throughput, or other unit parameters, as applicable).
- The emissions calculation tool was scaled from unit level information to estimate impacts across the geographic region.
- Emission calculations utilized information from evaluated research, the Demand Study, the Leakage Study, and other Phase 1 feasibility studies.

Emissions minimization opportunities can be implemented to reduce GHG (i.e., N_2O) emissions including equipment design opportunities, pre-mixing of air and fuel, management of air to fuel ratio to control combustion temperature, and emerging exhaust gas aftertreatment technologies. N_2O control equipment options also include existing technologies such as SCR and SNCR. Detailed information is available in the excel spreadsheets found in Appendix C.

4 BACKGROUND INFORMATION

4.1 PROPERTIES OF HYDROGEN

To effectively quantify greenhouse gas emissions from hydrogen combustion, one must fully grasp its unique combustive properties and the implications for GHG formation. Hydrogen has unique combustive properties that have the potential to eliminate the formation of GHG when combusted. Hydrogen offers a high energy content per mass and stands as a promising zero-carbon fuel, crucial in a carbon-reduced economy. Its broad flammability range allows operation across diverse air-to-fuel ratios from 34:1 to 180:1.[35] However, hydrogen's low ignition energy and high autoignition temperature may heighten the risk of flashback.[36] [37] Furthermore, hydrogen's high diffusivity helps in achieving even air-to-fuel mixtures, somewhat mitigating leakage-related safety concerns. Nevertheless, its low density means that a much greater volume is required to produce the same energy output as conventional fuels like natural gas.

4.2 REGULATORY INFORMATION

In the evolving landscape of energy regulation, both federal and state initiatives play a crucial role in shaping the future of Angeles Link and further deployment of hydrogen as a sustainable fuel. These policies, aimed at aligning energy production with environmental goals, are instrumental in reducing greenhouse gas emissions. The following discussion offers an in-depth examination of these legislative and regulatory measures.

Federal Legislation and Initiatives

- **Energy Policy Act of 2005[38]:** This Act supported diverse energy initiatives with provisions that specifically encouraged the development and use of hydrogen technology. It aimed to reduce dependency on fossil fuels and stimulate the commercialization of new energy technologies.

- **Energy Independence and Security Act of 2007[39]:** This legislation expanded the support for renewable fuels, including hydrogen, and required the periodic reevaluation of fuel economy standards, which are crucial for reducing the consumption of petroleum-based fuels and encouraging the use of cleaner alternatives.
- **Infrastructure Investment and Jobs Act of 2021[40]:** This Act included funding for the development of clean hydrogen hubs, which are intended to accelerate the deployment of hydrogen as a mainstream energy source and demonstrate its viability across different sectors.
- **Inflation Reduction Act (IRA) of 2022[41]**: The IRA passed in August 2022 provides a ten-year Production Tax Credit for clean hydrogen produced after December 31, 2022. The IRA defines tax credit tiers for “qualified clean hydrogen” with a well-to-gate GHG emission rate of less than 4.0 kilograms CO_2e per kilogram hydrogen.

Regulatory Developments

- **The U.S. Department of Energy:** Established the Clean Hydrogen Production Standard, targeting lifecycle greenhouse gas (GHG) emissions of ≤ 4.0 kg CO_2 equivalent per kilogram of hydrogen produced. This standard aims to ensure that hydrogen production is aligned with environmental goals.[42]
- **The Department of Treasury**: Drafted requirements for how to calculate carbon intensity, and to determine eligibility for the new tax credits under Section 45V, which will impact financial incentives for cleaner hydrogen production.[43]
- **The U.S. Environmental Protection Agency:** Is updating regulations under the Clean Air Act[44] to promote the adoption of low-GHG hydrogen, ensuring that the integration of hydrogen technologies does not adversely affect air quality.

California State Legislation and Policies:

- **Global Warming Solutions Act of 2006 (AB 32)**[45]: Set ambitious targets for GHG reductions, mandating that California's GHG emissions return to 1990 levels by 2020. This act positions the state as a leader in climate action, directly influencing the adoption of cleaner technologies including hydrogen.
- **Senate Bill 32 (SB 32)**[46]: Extends the goals of AB 32 by targeting a 40% reduction in GHG emissions from 1990 levels by 2030, further pushing the need for innovative energy solutions like hydrogen.
- T**he Clean Energy and Pollution Reduction Act of 2015 (SB 350)**[47]: This Act advances California's energy policy by setting ambitious targets for renewable energy adoption and energy efficiency, aiming to increase the procurement of renewable energy sources to 50% by 2030 and doubling energy efficiency savings in electricity and natural gas end uses.
- **The 100 Percent Clean Energy Act of 2018 (SB 100)[48]:** This legislation establishes a policy that 100 percent of the state's electricity should come from clean energy sources by 2045 and increased the renewable portfolio standard, indicating that 60% of electricity must be generated from eligible renewable resources by 2030, which directly impacts the hydrogen sector as part of the broader clean energy strategy.
- **Assembly Bill 197 (AB 197)**[49]: Focuses on direct emission reductions and requires public transparency in emission data, which supports informed decision-making and accountability in emission management.
- **California Climate Crisis Act of 2022 (AB 1279)**[50]: Sets a long-term goal for achieving carbon neutrality by 2045, underscoring the state's commitment to drastic reductions in GHG emissions through policies including the support for renewable energy sources like hydrogen.

- **2021 Senate Bill 643:** Requires the CEC, CARB, and CPUC to assess the hydrogen infrastructure and fuel production required for the transition to zero emission vehicles.[51] Some manufacturers are developing prototype equipment and are hoping that their equipment can ultimately qualify as a Zero Emission Vehicle (ZEV) under CARB's Advanced Vehicle regulations. However, at this time, the only vehicle types that qualify as ZEVs are electric vehicles and hydrogen fuel cell vehicles.
- **Zero Emissions for California Ports (ZECAP):** A program funded by CARB with GTI Energy to develop and demonstrate zero-emission hydrogen fueled yard trucks at the Port of Los Angeles (POLA). Capacity Trucks built two hydrogen-fueled yard trucks, powered by Ballard fuel cell engines that were then tested at the TraPac Terminal at POLA for one year. The hydrogen-fueled yard trucks operated successfully and with 2.5 to 3 times the efficiency of conventional diesel powertrains.[52] [53]
- **Clean Air Action Plan (CAAP)** for the Port of Los Angeles and the Port of Long Beach sets targets for 100% ZEVs for cargo handling equipment by 2030.[54]
- **Commercial Harbor Crafts:** For new or replacement short-run ferries or excursion vessels, after January 1, 2023, the Commercial Harbor Craft Regulation requires that they meet Zero Emissions Advanced Technology (ZEAT).[55]
- **Cargo Handling Equipment:** The San Pedro Bay Ports Complex issued an initial CAAP in 2017 outlining their goal of achieving 100% ZEVs for cargo handling equipment by 2030, earlier than California's goal of zero emissions from mobile sources by 2035 established in EO N-79-20.[56] CARB has proposed to begin the transition to ZEVs for cargo handling equipment in 2026.[57] The CAAP requires that a feasibility assessment for zero-emission and near zero-emission cargo-handling

equipment be completed every three years. In 2020, Hyster-Yale Group entered into a partnership with Capacity Trucks to develop hydrogen yard trucks.[58] Conductix Wampfler is in the concept design stage for a hydrogen fuel cell-powered RTG crane.[59]

- A proposal has been published to implement a **Zero Emission Forklift** rule in California as part of CARB's Mobile Source Strategy, State Implementation Plan, and Sustainable Freight Action Plan.[60]
- **Funding Agricultural Replacement Measures for Emission Reductions (FARMER):** This program has been implemented using funds from the cap-and-trade program to invest in research and development into zero emissions agricultural vehicles.[61]
- **Advanced Clean Cars II Regulation[62]**: This regulation requires an increasing number of zero-emission vehicles, including battery electric, hydrogen fuel cell electric and plug-in hybrid electric vehicles, to meet air quality and climate change emissions standards and requires all new passenger vehicles sold in California to be zero emissions by 2035.
- **AB 8:** This legislation required 20 percent of CEC's Clean Transportation Program funding be dedicated to hydrogen refueling stations until there are 100 open retail stations. It also required the CEC and CARB to jointly review and report on progress toward establishing a hydrogen fueling network that provides the coverage and capacity to fuel vehicles requiring hydrogen fuel.[63]

- **Executive Order B-48-18**[64]: This Executive Order ordered state entities to work with the private sector and all appropriate levels of government to spur construction and installation of 200 hydrogen fueling stations and 250,000 ZEV chargers, including 10,000 DC fast chargers, by 2025.
- **AB 1493**[65]**, SB X1-2**[66]**, and SB 535**[67]: These legislative measures address climate change by setting standards for vehicle GHG emissions, ensuring benefits from climate investments reach disadvantaged communities, and supporting the transition to a sustainable energy economy.
- **CARB 2022 Scoping Plan**[68]**:** This comprehensive strategy details actions for increasing the adoption of zero-emission vehicles, expanding renewable energy use, enhancing the cap-and-trade program to incentivize emission reductions, and developing carbon capture and storage technologies. It emphasizes fairness in the distribution of environmental benefits and burdens, particularly in pollution-impacted communities.
- **Advanced Clean Trucks and Advanced Clean Fleet regulation**[69] [70]**:** These regulations aim to accelerate the transition of medium- and heavy-duty vehicles to zero-emission vehicles, including hydrogen-fueled options, in both public and private transport sectors.

[70] CARB, 2024c, Innovative Clean Transit Regulation, https://ww2.arb.ca.gov/our-work/programs/innovative-clean-transit/about

- **Clean Miles Standard[71] and Innovative Clean Transit rule[72]**: These initiatives specifically promote zero-emission standards in public and commercial transportation, enhancing the role of hydrogen and other clean energy sources in reducing emissions from the transport sector.
- **Sector-Specific Regulations**: Include regulations like the Zero Emission Airport Shuttle Rule[73] and a proposal has been published to implement a Zero Emission Forklift rule in California.[74]
- **Additional Legislative Efforts Focusing on Hydrogen**: Bills such as SB 1075[75], which mandates a thorough evaluation of hydrogen's role in California's energy landscape, and SB 414[76], which requires an assessment of hydrogen applications, are crucial for framing the state's hydrogen strategy. SB 746, which proposes to include hydrogen as an alternate energy source in energy conservation contracts, is also important.[77]

These actions have established California as a leader in promoting renewable fuels and zero-emission technologies, influencing policies across various sectors including transportation and energy.

Feedback from stakeholders such as the Los Angeles Department of Water and Power (LADWP) and the South Coast Air Quality Management District (South Coast AQMD) has emphasized the technological and regulatory challenges in adopting hydrogen. These concerns highlight the need for ongoing adjustments to regulatory approaches to accommodate technological advancements and ensure effective emission reductions.

4.3 TECHNOLOGY DEVELOPMENTS

Manufacturers are advancing technology to enable combustion engines to function entirely on hydrogen, targeting applications in power generation, industrial heating, and transportation. Currently, smaller turbines such as Siemens' SGT-A35, with a capacity of 30-40 MW, and the SGT-400, rated at 10-15 MW, already operate on 100% hydrogen.[78] However, larger turbine models still require technological enhancements to sustain full hydrogen operation and maintain low air pollution levels. The leading manufacturers in this sector are Siemens, General Electric (GE), Solar, and Mitsubishi.

Both Siemens and GE are working towards developing large, advanced turbines that can achieve 100% hydrogen combustion by 2030. In 2022, the DOE provided financial assistance to manufacturers to develop hydrogen turbine combustion technology through the Industry Advanced Turbine Awards. The manufacturers who received these awards included GE for their H_2 F-Class retrofits, Solar Turbines for their GT Comb System for hydrogen and natural gas blends, and GE Research for their GT-Scale RDC Demo at 7FA cycle condition.[79]

Mitsubishi aims to reach this capability by 2025 and has already made progress; in 2018, their proprietary burner technology in Mitsubishi Hitachi Power Systems achieved a 10% reduction in CO_2 emissions with a 30% hydrogen blend.[80,81]

GE categorizes its turbines into four groups based on their hydrogen handling capacity: Aeroderivative, B/E-Class, F-Class, and HA-Class. Per GE Vernova, gas turbines are inherently fuel flexible and can be configured to use clean renewable hydrogen as new units or units upgraded after service using natural gas. Aeroderivative, B/E-Class and F-Class can currently handle up to 100% hydrogen and the HA-Class can currently handle 50% and is expected to be able to handle 100% hydrogen in the future.[82]

Siemens has also demonstrated the adaptability of their turbines to hydrogen: the Aeroderivative SGT-A35 turbines can operate on 100% hydrogen using special burners.[83] More recently, in 2023, Siemens announced that their SGT-400 unit, with a 10-15 MW

5 ASSUMPTIONS AND RESULTS BASED ON DEMAND STUDY

This section summarizes GHG emissions calculations based on the Demand Study, aiming to project annual GHG emissions reductions for each year from 2030 to 2045. These results are grouped by infrastructure and by end-user sectors. Detailed emission calculations are provided in the Appendix to this Final Report. The analysis considers the following categories for projected GHG emissions:

- Infrastructure: This includes the production, storage, and transmission of hydrogen to end-users.
- End-Users: Covers mobility, power generation, and hard-to-electrify industrial sectors that are projected to utilize hydrogen.

Methodology: The methodology aggregates emissions reductions totals for each end-user subsector to derive totals for each sector. These sectoral totals are then summed with the anticipated GHG emissions from the new infrastructure to estimate overall annual GHG emissions reductions for the target years.

5.1 INFRASTRUCTURE

The results for potential GHG emission increases from new hydrogen infrastructure based on the conservative and ambitious demand scenarios for 2045 are up to 0.17% and 0.25% the magnitude of end-user reductions for these same scenarios.

5.1.1 Hydrogen Production (Third-Party)

Three equipment options were evaluated for hydrogen production to meet the definition of clean renewable hydrogen.

1. Electrolyzers powered by renewable electricity: zero GHG emissions.
2. Biomass gasification: zero GHG emissions[87]
3. RNG SMR (Renewable Natural Gas Steam Methane Reforming) with hydrogen as combustion fuel for heater: Could include some GHG emissions in the form of trace amounts of N_2O.

Multiple scenarios were evaluated with varying contributions to total production by each of the three types of equipment listed above to estimate the range of potential GHG emissions. The estimated emissions range from zero GHG associated with the 100% electrolysis and the 100% biomass gasification scenarios to the potential for some GHG emissions for the 100% RNG SMR scenario as detailed below. These estimates can be refined as more detailed project information from third-party producers becomes available, particularly regarding production processes and the proportions of hydrogen

[87] The Study only considered biomass gasification that uses a process that is carbon neutral.

produced from different methods. Estimated GHG emission results are provided for the conservative and ambitious demand scenarios in Table 3.

Table 3 presents the projected GHG emissions from hydrogen production technologies based on the conservative and ambitious demand scenarios. This table categorizes emissions into minimum and maximum estimates in five-year increments from 2030 to the year 2045. For the conservative demand scenario, the estimates range from 1,120 MT CO2e in 2030 to 16,245 MT CO2e in 2045, based on 100% use of Steam Methane Reforming (SMR) with Renewable Natural Gas (RNG). For the ambitious demand scenario, the estimates range from 9,448 MT CO2e in 2030 to 50,080 MT CO2e by 2045 under the 100% RNG SMR scenario. In contrast, the low estimates demonstrate zero emissions across all years, reflecting scenarios where 100% of hydrogen production is achieved through electrolysis or biomass gasification.

Table 3
Potential Direct GHG Emissions from Hydrogen Production Based on Demand Scenarios

Demand Scenario	Emissions (MT CO_2e/yr)				Production Scenario
	2030	2035	2040	2045	
Conservative Max	1,120	4,448	9,552	16,245	100% SMR (Max Case)
Conservative Min	0	0	0	0	100% Electrolysis or Biomass Gasification
Ambitious Max	9,448	19,565	33,369	50,080	100% SMR (Max Case)
Ambitious Min	0	0	0	0	100% Electrolysis or Biomass Gasification

5.1.2 Storage (Third-Party) and Transmission

For the storage and transmission of hydrogen, the following three types of compressors were evaluated. Further details regarding compressors being considered are available in the parallel Phase 1 Pipeline Sizing and Routing Study.

1. Electric Motor-Driven Compressors: These utilize electricity from renewable sources, resulting in zero GHG emissions.
2. Hydrogen-Fueled Reciprocating Engine Driven Compressors: Emits no CO_2. However, trace amounts of N_2O could form from the nitrogen present in the combustion air at specific temperatures.

3. Hydrogen-Fueled Turbine Driven Compressors: Similar to reciprocating engines, these compressors could also emit trace amounts of N_2O.

Emissions of GHG (as N_2O) from hydrogen fueled reciprocating engine driven compressors and from turbine driven compressors were conservatively estimated using equation 1:

*Fuel Throughput x Emissions Factor * GWP = GHG Emissions (equation 1)*

The first equation (equation 1) multiplies the quantity of clean renewable hydrogen by the N_2O emission factor assumed in this Study for hydrogen. The emissions for N_2O are then multiplied by the GWP as shown in Table 1 to determine GHG emissions in units of CO2e.

This evaluation assumed that storage requirements would be similar between hydrogen and natural gas to accommodate fluctuations in fuel supply and demand. Data from 2022 from the "2023 California Gas Report Supplement"[88] was used to estimate a California-specific value for the fraction of annual hydrogen demand that would be stored. From this source, it was determined that the average quantity of supplied natural gas in California during 2022 was 6,023 MMcf/day, which equates to approximately 2,198 Bcf/yr. This source also indicated that in 2022 California had a natural gas storage capacity of approximately 304 Bcf. Dividing these two values yielded a maximum (conservative) fraction of annual natural gas demand that would be stored: 13.8%. This value was applied to hydrogen; therefore, it was assumed that annually 13.8% of hydrogen demand would be stored.

The Study evaluates two storage pressure scenarios—290 psi (low pressure) and 2,900 psi (high pressure). These were developed based on an article that presented a variety of hydrogen storage options and their corresponding pressures. The highest and lowest pressures from this publication were utilized to represent the full range of potential storage pressures, and therefore storage compressor energy demands, from this project. These low and high storage pressure scenarios were 20 bar (290 psi) and 200 bar (2,900 bar) respectively.[89] The energy needed to store hydrogen at 290 psi and 2,900 psi was determined to be 4 megajoules (MJ)/kg and 14 MJ/kg, respectively.

The Study also assumed a transmission distance of 450 miles based on information provided by the Pipeline Sizing and Routing Study. Efficiency values for reciprocating engines and turbines were also sourced from scientific literature to convert fuel energy in

88 CPUC, 2023, 2023 California Gas Report Supplement prepared per Decision D.95-01-039, https://www.socalgas.com/sites/default/files/Joint_Biennial_California_Gas_Report_2023_Supplement.pdf

89 Tahan, M., 2022, Recent advances in hydrogen compressors for use in large-scale renewable energy integration, International Journal of Hydrogen Energy 47(83): 35275-35292, https://doi.org/10.1016/j.ijhydene.2022.08.128

units of MMBtu to energy supplied by power sources for compression in units of MJ. These efficiency values were 60.3% and 51.9% for hydrogen fueled reciprocating engines and turbines respectively. Please refer to the Pipeline Sizing and Routing Study for additional information.

These parameters are preliminary assumptions being used since detailed design data is not available for this feasibility study. Future refinements in GHG emission estimates could incorporate more specific details on compressor types, sizes, and quantities, as well as assumptions about storage volumes and pressures. Additionally, development of assumptions regarding aboveground and underground storage volumes and pressures can support development of refinement of GHG emission estimates.

Results for storage and transmission for GHG emissions are provided for the conservative demand scenario in Tables 4 and 5, respectively. Table 4 displays the emissions from hydrogen storage at two pressure levels based on the conservative demand scenario. For high-pressure storage using turbine-driven compressors, emissions rise from 204 MT CO2e in 2030 to 2,959 MT CO2e in 2045. Based on the ambitious demand scenario, the values range from 1,200 MT CO2e in 2030 to 10,599 MT CO2e in 2045. When electric motor-driven compressors are used at any pressure, the emissions remain at zero throughout the study period.

Table 4
Potential Direct GHG Emissions from Hydrogen Storage Based on Demand Scenarios

Demand Scenario	Emissions (MT CO_2e/yr)				Scenario	
	2030	2035	2040	2045	Storage Pressure	Power Source
Conservative Max	204	810	1,740	2,959	2,900 psi	Turbine
Conservative Min	0	0	0	0	All Pressures	Renewable Electricity
Ambitious Max	2,000	4,141	7,062	10,599	2,900 psi	Turbine
Ambitious Min	0	0	0	0	All Pressures	Renewable Electricity

Table 5 presents the emissions associated with using compressors to support transmission of hydrogen over a 450 mile distance. For hydrogen-fueled compressors, the emissions increase from 609 MT CO2e in 2030 to 8,829 MT CO2e by 2045 for the conservative demand scenario. Emissions for hydrogen transmission using hydrogen-fueled compressors are estimated at 5,135 MT CO2e in 2030 and 27,220 MT CO2e by 2045 for the ambitious demand scenario. When using electric motor-driven compressors powered by renewable electricity, the emissions are maintained at zero.

Table 5
Potential Direct GHG Emissions from Hydrogen Transmission Based on Demand Scenarios

Demand Scenario	Emissions (MT CO_2e/yr)				Scenario	
	2030	2035	2040	2045	Transmission Distance	Power Source
Conservative Max	609	2,418	5,192	8,829	450 miles	Hydrogen
Conservative Min	0	0	0	0	All Distances	Renewable Electricity
Ambitious Max	5,135	10,634	18,137	27,220	450 miles	Hydrogen
Ambitious Min	0	0	0	0	All Distances	Renewable Electricity

5.2 END USERS

Consistent with the Decision, Angeles Link is intended to transport clean renewable hydrogen to multiple end user sectors. The focus of the GHG emissions study was on three sectors of end-users identified in the parallel Demand Study: mobility, power generation, and hard to electrify industrial. The Demand Study estimated quantities of diesel and gasoline that may be displaced by hydrogen fuel cells in the mobility sector. The Demand Study also estimated quantities of natural gas that may be displaced by hydrogen fuel in the power generation and hard to electrify industrial sectors.

As described in the Routing Analysis, SoCalGas's route selection process evaluates directional pathways that account for engineering, environmental, social, and environmental justice features along four potential preferred routes. A final preferred route will be selected in Phase 2 of Angeles Link. Once the final preferred route is selected, more specific details regarding potential end users can be developed.

The potential for leakage at end users was not quantified as part of this study; and the minimal information regarding leakage at end users that was available in the literature was added to Section 4.1.1 of the Leakage Study.

5.2.1 Mobility

Mobility is the largest end-user sector for GHG emission reductions, accounting for 72.5% and 50.3% of overall reductions in 2045 for the conservative and ambitious demand scenarios, respectively, due to the substitution of hydrogen fuel cells for fossil fuels. Potential sources of GHG emissions in this sector include on-road vehicles such as heavy-duty vehicles (HDV), medium-duty vehicles (MDV), and buses. For example, the 'Zero Emission Bus Transition Plan' specifically targets AC Transit in Oakland, California, focusing on deploying hydrogen fuel cells and electric buses to advance its long-standing public transit services.[90] The Mobility sector also includes off-road vehicles in Agriculture, Commercial Harbor Craft (CHC), Cargo Handling Equipment at ports (CHE), Construction and Mining, and Ground Support Equipment at airports (GSE).

- Conservative Demand Scenario, 2045
    - On-Road Vehicles account for 93.9% of Mobility GHG emission reductions
        - Heavy Duty Vehicles are 58.5% of Mobility GHG reductions for the year 2045.
    - Off-Road Vehicles account for 6.1% of Mobility GHG emission reductions
- Ambitious Demand Scenario, 2045
    - On-Road Vehicles account for 94.6% of Mobility GHG emission reductions
        - Heavy Duty Vehicles are 62.8% of Mobility GHG reductions for the year 2045.
    - Off-Road Vehicles account for 4.4% of Mobility GHG emission reductions

The assumptions for the Mobility sector are primarily that diesel and gasoline fuel will be displaced, and vehicles would convert to hydrogen fuel cells with zero emissions. Emission factors for GHG from displaced diesel and gasoline fuel were developed using EMFAC data. The EMFAC model contains sufficient data to estimate CO_2, CH_4, and N_2O emissions for on-road mobile sources, and CO_2 emissions for off-road mobile sources. The EMFAC model does not include CH_4 and N_2O emissions data for off-road mobile vehicles. Research was conducted to estimate the most representative CH_4 and N_2O emissions factors for off-road mobile sources. Fuel consumption was weighted by subcategory of vehicle types. The same two equations previously mentioned were used to conduct the GHG calculations, and the hydrogen emissions value in equation 2 is zero.

*Fuel Throughput x Emissions Factor * GWP = GHG Emissions (equation 1)*

GHG Emission Reductions = Fossil Fuel GHG Emissions – Hydrogen GHG Emissions (equation 2)

[90] AC Transit, Zero Emission Bus Transition Plan, 2022, https://www.actransit.org/sites/default/files/2022-06/0162-22%20ZEB%20Transition%20Plan_052022_FNL.pdf (actransit.org)

The total emissions were calculated by summing totals for each equipment type and are shown in Table 6. Figures 2A and 2B provide graphs for the conservative and ambitious demand scenarios, respectively below. The GHG reductions estimated for the conservative demand scenario in 2045 are equivalent to approximately 2.7 million gasoline passenger vehicles driven for one year per EPA Calculator. The GHG reductions estimated for the ambitious demand Scenario in 2045 are equivalent to over 4 million gasoline passenger vehicles driven for one year per EPA Calculator.

Table 6
Mobility Direct GHG Combustion Emission Reductions (million MT CO_2e/yr)

Demand Scenario	2030	2035	2040	2045
Conservative	0.94	3.81	7.84	12.14
Ambitious	4.44	9.04	13.97	17.98

Table 6 illustrates the expected reductions in GHG emissions within the mobility sector, under conservative and ambitious demand scenarios, spanning from 2030 to 2045. In the conservative demand scenario, GHG reductions are substantial, beginning at approximately 939 thousand metric tons of CO_2 equivalent (MT CO2e) in 2030 and increasing by more than ten-fold to over 12 million MT CO2e by 2045. This increase reflects a growing adoption of hydrogen-fueled mobility solutions. Under the ambitious demand scenario, the reductions are even more pronounced, starting at about 4.4 million MT CO2e in 2030 and escalating to nearly 18 million MT CO2e by 2045. These figures suggest a robust integration of hydrogen in transportation, cutting GHG emissions as the Mobility sector transitions away from fossil fuels.

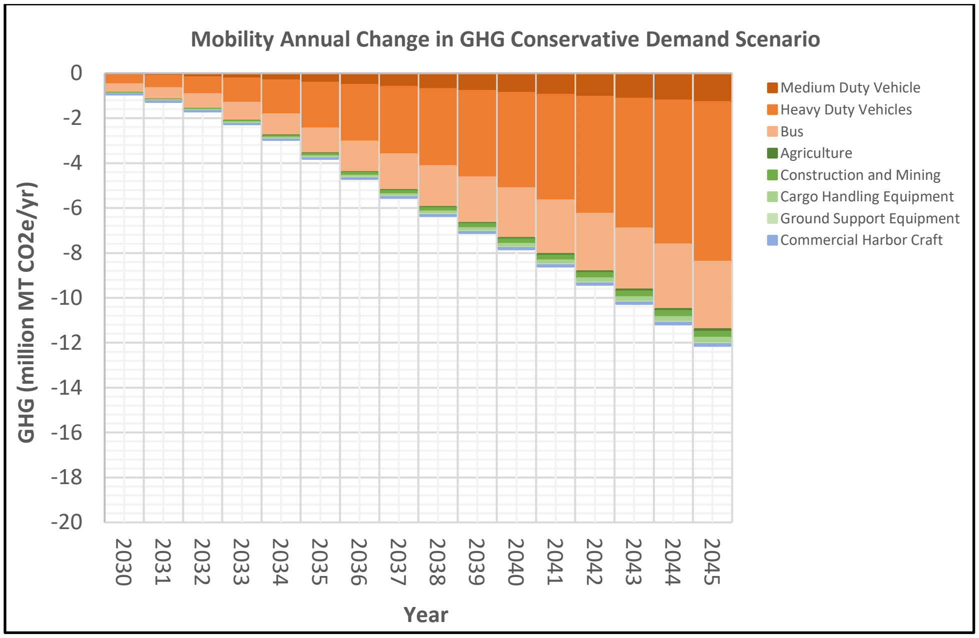

Figure 2A. Mobility Annual Change in GHG - Conservative Demand Scenario

Figure 2A visualizes the annual change in GHG emissions for the Mobility sector under the conservative demand scenario over the period from 2030 to 2045. The chart shows a steady decline in GHG emissions, with the largest reductions seen in heavy-duty vehicles. Medium-duty vehicles, buses, and other categories such as Agriculture and Construction contribute to the overall decrease but to a lesser extent. This trend reflects the potential impact of deploying clean hydrogen fuel cell technology in reducing emissions from various subsectors within mobility, with the most substantial effect seen in the heavy-duty vehicle category.

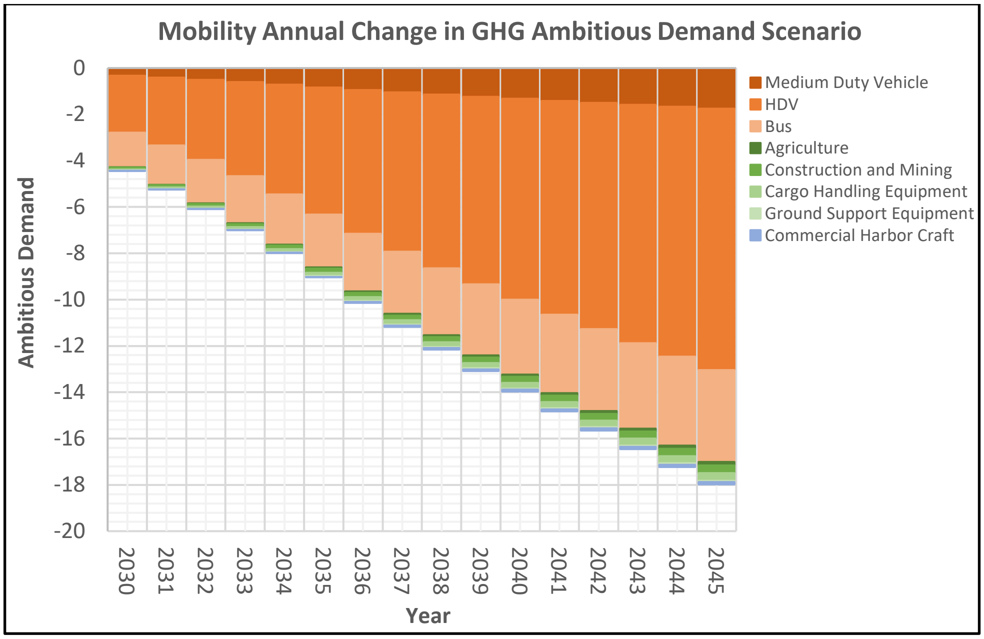

Figure 2B. Mobility Annual Change in GHG - Ambitious Demand Scenario

Figure 2B presents the changes in GHG emissions in the ambitious demand scenario, which assumes higher shift towards hydrogen fuel cell vehicles across the Mobility sector. The decreasing stacked bars, which represent different vehicle categories, indicate an even more pronounced annual decrease in GHG emissions compared to the conservative demand scenario. Heavy-duty vehicles remain the largest contributors to GHG reductions, followed by medium-duty vehicles and buses. The chart illustrates a potential future where a ambitious demand for hydrogen in the mobility sector could lead to much lower GHG emissions, showcasing the Mobility sector's pivotal role in achieving broader climate targets.

5.2.2 Power Generation

The results for the anticipated GHG emissions reductions based on the conservative and ambitious demand scenarios data in 2045 are that the Power Generation sector accounts for 23.6% and 41.7% of overall GHG reductions, respectively. The assumptions that were applied to develop the GHG emissions calculations include that hydrogen will displace natural gas as a fuel with increasing amounts over time (from 2030 to 2045). The potential for leakage at power generation end users such as when hydrogen is transferred from onsite storage or pipelines to onsite hydrogen combustion equipment is acknowledged but was not quantified as part of this study.

This Study is focused on estimating GHG emissions reductions anticipated to be associated with use of clean renewable hydrogen as a fuel in the power generation sector relating to the development of Angeles Link. At the time of this Study, there is not sufficient detailed project information to estimate the quantity of electricity anticipated to be produced using 100% clean renewable hydrogen as the future annual average utilization and the capacity factor for thermal power plant generation is not known.

For each emission source type identified, calculations to estimate GHG emissions were prepared using the same two equations previously mentioned.

*Fuel Throughput x Emissions Factor * GWP = GHG Emissions (equation 1)*

GHG Emission Reductions = Fossil Fuel GHG Emissions – Hydrogen GHG Emissions (equation 2)

The first equation (equation 1) multiplies the quantity of fuel by the GHG emission factor specific to the fuel for each GHG pollutant. These pollutants are CO_2, CH_4, and N_2O for combustion of fossil fuels and trace amounts of N_2O for combustion of hydrogen. Each GHG has a specific fuel dependent emission factor and a unique GWP as shown in Table 1. The emissions for each of CO_2, CH_4, and N_2O are multiplied by their respective GWP and then summed to obtain the total GHG emissions in units of CO2e.

The second equation (equation 2) calculates the GHG emission reductions in CO2e by subtracting the GHG emissions for hydrogen (either for N_2O from combustion of hydrogen or zero for hydrogen fuel cells) from the GHG emissions for combustion of displaced fossil fuels. The GHG emissions for combustion of hydrogen and for combustion of fossil fuels are both derived from equation 1.

As previously noted, for combustion of clean renewable hydrogen, GHG is comprised entirely of N_2O from the nitrogen present in the combustion air at specific temperatures, and since the GWP 20 and GWP 100 for N_2O are both 273, the expected impacts in both short term and long term should be similar. The total emissions were calculated by summing totals for each equipment type and are shown in Table 7. Detailed information is available in the excel spreadsheets found in Appendix C.

Table 7
Power Generation Direct GHG Combustion Emission Reductions
(million MT CO_2e/yr)

Demand Scenario	2030	2035	2040	2045
Conservative	0.04	0.61	1.87	3.95
Ambitious	0.16	2.30	7.06	14.90

Table 7 quantifies the projected reductions in GHG emissions within the Power generation sector for both conservative and ambitious demand scenarios from 2030 to 2045. In the conservative demand scenario, the reductions begin modestly at 0.04 million MT CO2e in 2030, gradually escalating to 3.95 million MT CO2e by 2045, accounting for 23.6% of the overall anticipated GHG reductions. For the ambitious demand scenario, the reductions are greater, starting at 0.16 million MT CO2e and surging to 14.90 million MT CO2e by 2045, contributing to 41.7% of the total expected reductions. These estimates reflect the impact of transitioning to clean renewable hydrogen in Power generation, highlighting the sector's potential contribution to reducing GHG emissions.

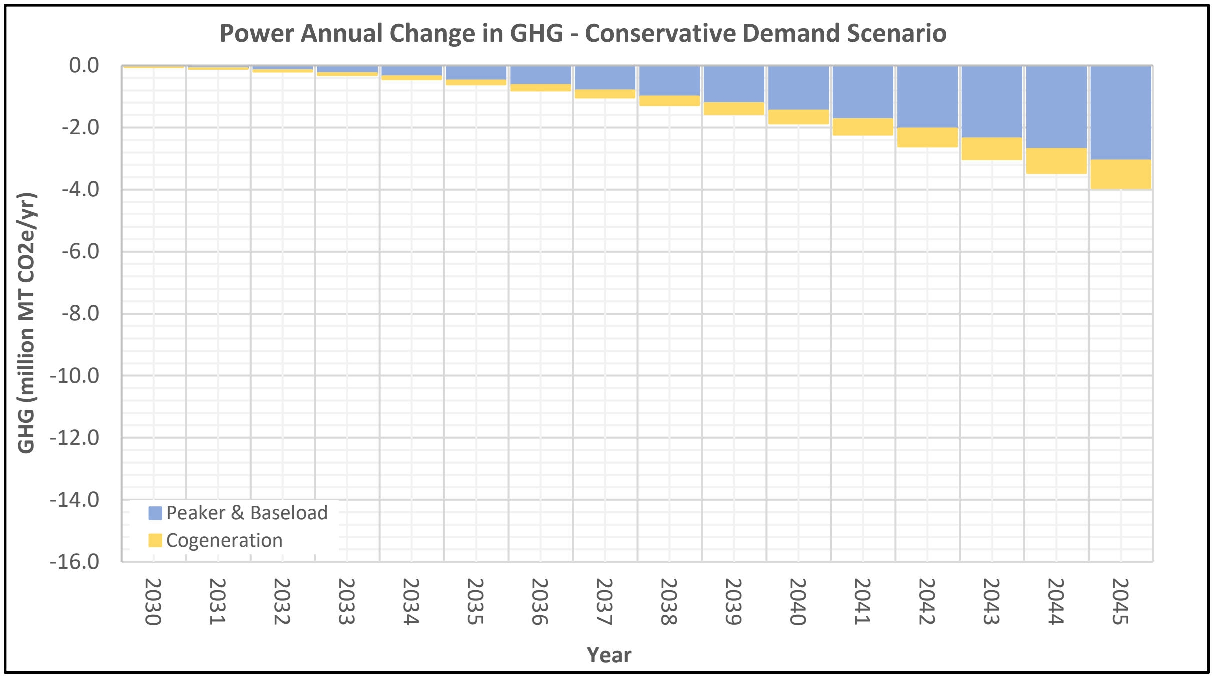

Figure 3A. Power Annual Change in GHG - Conservative Demand Scenario

Figure 3A represents the annual change in GHG emissions for the Power sector under the conservative demand scenario. It features two distinct segments in each bar: the larger, representing base load and peaker power generation units, and the smaller, cogeneration units. Together, they depict a downward trend in emissions, signaling a reduction in GHG as the sector pivots towards clean renewable hydrogen use. By 2045, this shift equates to the GHG emissions of over 769,537 households' annual electricity consumption.

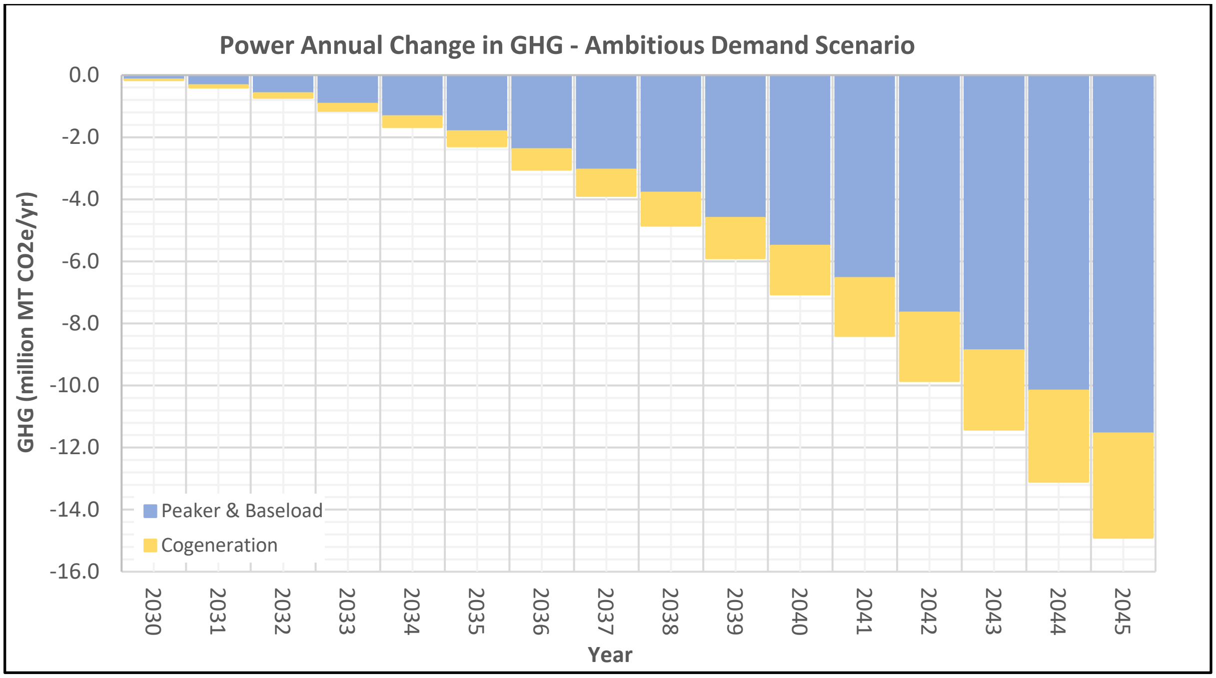

Figure 3B. Power Annual Change in GHG - Ambitious Demand Scenario

Figure 3B illustrates the Power sector's annual GHG emissions changes under the ambitious demand scenario, showing deeper reductions than the conservative demand scenario. This scenario implies a faster adoption of clean renewable hydrogen as a fuel source, with the dark blue and yellow bars representing peaker and base load and cogeneration units, respectively. The staggered bars mirror an increased decline in emissions year over year, culminating in a decrease comparable to the annual electricity use of nearly 2.91 million homes by 2045. This emphasizes the transformative potential of a high demand shift to clean renewable hydrogen fuel, substantially lowering the Power sector's carbon footprint.

5.2.3 Hard to Electrify Industrial

Hard to Electrify Industrial sectors include energy-intensive industries such as refining; food and beverage manufacturing; primary and fabricated metals; stone, clay, and glass (including cement); chemical manufacturing; wood and paper; petroleum products; mining; ammonia production; industrial launderers; co-generation; and textile manufacturing. These sectors are anticipated to initially blend hydrogen with natural gas in 2030 and then eventually transition to pure hydrogen by 2050. Source types with the potential for GHG emissions in the Hard to Electrify Industrial sectors include hot water boilers, steam generating units, process heaters, furnaces/kilns, reciprocating internal combustion engines, turbines, and miscellaneous combustion equipment.

The results for the anticipated GHG emissions reductions associated with the Industrial sector based on the conservative and ambitious demand scenario data in 2045 are that the Industrial sector accounts for 3.9% and 8.1% of overall GHG reductions, respectively. The assumptions that were applied to develop the GHG emissions calculations include that clean renewable hydrogen will displace natural gas as a fuel with increasing amounts over time (from 2030 to 2045). It should be noted that consistent with the Decision, Angeles Link is intended as a project to transport only 100% clean renewable hydrogen in the pipeline, and any analysis of hydrogen blending refers strictly to “behind-the-meter” operations, not within SoCalGas control. This Study does not dictate if end users will blend hydrogen with natural gas and makes assumptions regarding adoption rates based on currently available information regarding equipment and the anticipated evolution of adoption over time. Since only 100% clean renewable hydrogen will be delivered, to estimate GHG reductions at end users, assumptions regarding hydrogen adoption rates were made as shown in Tables 2A and 2B. The estimated emissions are based on these assumptions.

The potential for leakage at hard to electrify industrial end users such as when hydrogen is transferred from onsite storage or pipelines to onsite hydrogen combustion equipment is acknowledged but was not quantified as part of this study.

For each emission source type identified, calculations to estimate emissions were prepared using the same two equations previously mentioned.

*Fuel Throughput x Emissions Factor * GWP = GHG Emissions (equation 1)*

GHG Emission Reductions = Fossil Fuel GHG Emissions – Hydrogen GHG Emissions (equation 2)

The first equation (equation 1) multiplies the quantity of fuel by the GHG emission factor specific to the fuel for each GHG pollutant. These pollutants are CO_2, CH_4, and N_2O for combustion of fossil fuels and N_2O for combustion of hydrogen. Each GHG has a specific fuel dependent emission factor and a unique GWP as shown in Table 1. The emissions for each of CO_2, CH_4, and N_2O are multiplied by their respective GWP and then summed to obtain the total GHG emissions in units of CO2e.

The second equation (equation 2) calculates the GHG emission reductions in CO2e by subtracting the GHG emissions for hydrogen (either for N_2O from combustion of hydrogen or zero for hydrogen fuel cells) from the GHG emissions for combustion of displaced fossil fuels. The GHG emissions for combustion of hydrogen and for combustion of fossil fuels are both derived from equation 1.

As previously mentioned, for combustion of clean renewable hydrogen with GHG emissions comprised entirely of N_2O, since the GWP 20 and GWP 100 for N_2O are both 273, the expected impacts in both short term and long term should be similar.

The total emissions were calculated by summing the totals for each equipment type and are shown in Table 8. Figures 4A and 4B provide graphs for the conservative and ambitious demand scenarios, respectively below. The GHG reductions predicted for the conservative demand scenario in 2045 are equivalent to 139,007 homes' electricity use for one year per EPA Calculator. The GHG reductions predicted for the ambitious demand scenario in 2045 are equivalent to 603,582 homes' electricity use for one year per EPA Calculator. Detailed information is available in Appendix C.

Table 8
Hard-to-Electrify Industrial Direct GHG Combustion Emission Reductions (million MT CO_2e/yr)

Demand Scenario	2030	2035	2040	2045
Conservative	0.28	0.45	0.56	0.65
Ambitious	1.13	1.91	2.45	2.89

Table 8 focuses on the GHG emission reductions in the industrial sector, a variety of energy-intensive industries facing challenges in electrification. The table reflects emission reductions from 2030 through 2045 under conservative and ambitious demand scenarios. Under the conservative demand scenario, reductions start at 0.28 million MT CO2e in 2030, modestly increasing to 0.65 million MT CO2e by 2045. This change represents a steady progression towards cleaner energy usage within these industries, accounting for 3.9% of the overall GHG reduction. In contrast, the ambitious demand scenario starts at 1.13 million MT CO2e in 2030, ramping up to 2.89 million MT CO2e by 2045, indicating more aggressive adoption rates of clean renewable hydrogen as a replacement for natural gas, contributing to 8.1% of total GHG reductions. The trajectory of both scenarios suggests an evolving industrial landscape where clean renewable hydrogen plays a key role in reducing emissions.

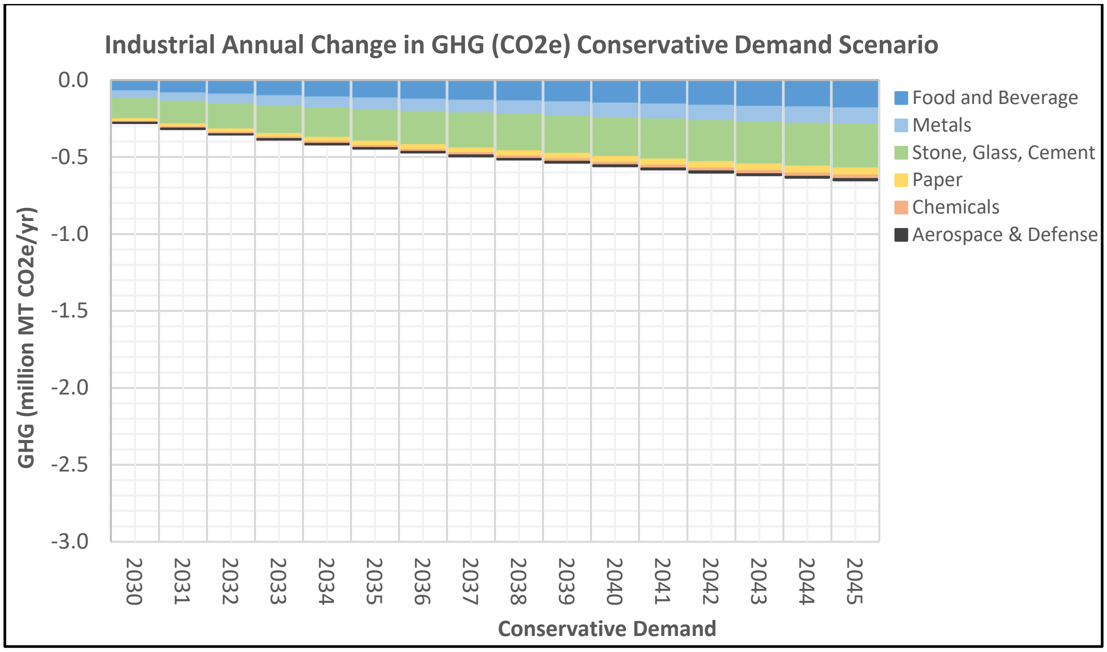

Figure 4A. Industrial Annual Change in GHG - Conservative Demand Scenario

Figure 4A visualizes the decline in GHG emissions across various sub-sectors in the industrial sector for the conservative demand scenario. It showcases how industries like food and beverage, metals, and others are expected to reduce their emissions over the years, with the most substantial decreases projected in the refining sector. The total projected GHG emission reductions in 2045 are equivalent to the annual electricity usage of about 139,000 homes.

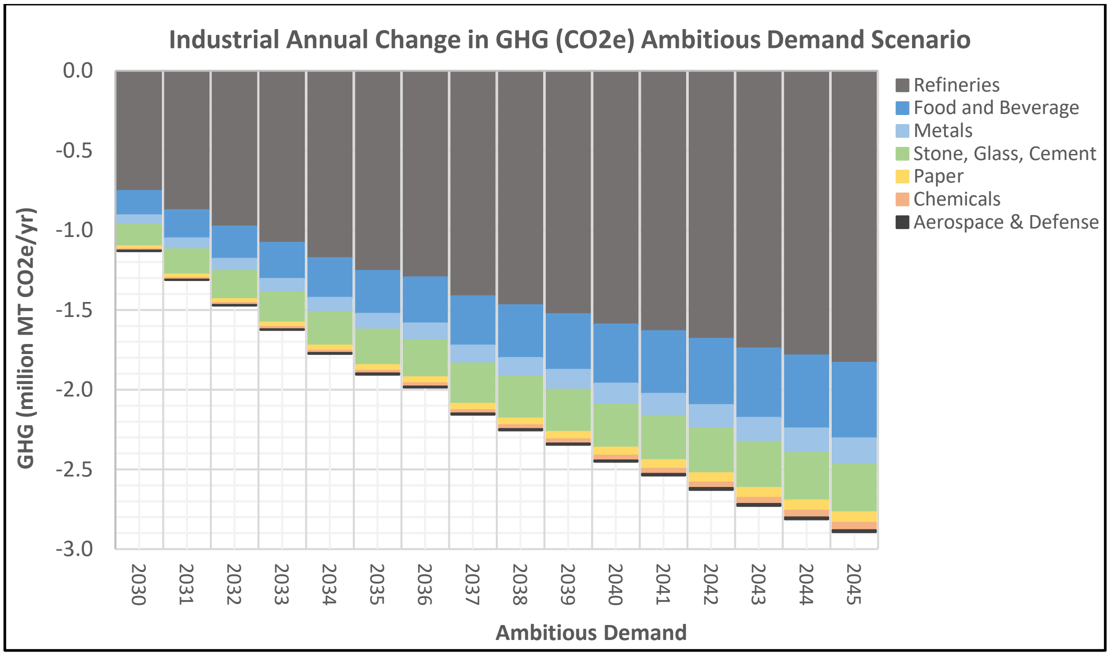

Figure 4B. Industrial Annual Change in GHG – Ambitious Demand Scenario

Figure 4B depicts a larger reduction in GHG emissions within the industrial sector under the ambitious demand scenario. The larger scale of reductions mirrors a more robust transition to clean renewable hydrogen fuel, with the refining sector again making up the largest proportion of decreases. The graph indicates that the industrial sector could achieve GHG reductions in 2045 equating to the yearly electricity use of 603,582 homes. This scenario emphasizes the sector's potential for substantial contributions to overall emission reductions with an intensified hydrogen adoption rate.

6 OVERALL RESULTS BASED ON DEMAND STUDY SCENARIOS

The anticipated potential minor GHG emissions associated with the new infrastructure were added to the overwhelmingly large anticipated GHG emissions reductions associated with potential end users of clean renewable hydrogen as defined by the Demand Study.[91] The total GHG reductions predicted for the conservative demand scenario in 2045 for end-users are equivalent to more than 3,255,000 homes' electricity use for one year per EPA Calculator. The total GHG reductions predicted for the ambitious demand scenario in 2045 for end-users are equivalent to more than 6,961,000 homes' electricity use for one year per EPA Calculator. The results are provided in Table 9 and in Figures 5A and 5B below. Detailed information is available in the excel spreadsheets found in Appendix C.

In summary:

- Projected up to nearly 17 and 36 million metric tons of CO2e removed per year from SoCalGas territory geographic area by end users by 2045 for conservative and ambitious demand scenarios, respectively.
- Infrastructure GHG emissions are smaller than end-user reductions.
    - The highest potential infrastructure GHG emissions estimated are 0.17% and 0.25% the magnitude of overall end-user reductions for conservative and ambitious demand scenarios, respectively, in 2045.
- Mobility GHG emissions would be eliminated with clean renewable hydrogen substitution when fossil fuels are replaced with hydrogen fuel cells. In the Mobility sector, hydrogen fuel cells offer a substantial reduction in GHG emissions by replacing diesel and gasoline in vehicles. This sector shows the highest reduction potential due to the large contributions to emissions by heavy-duty and medium-duty vehicles using traditional fuels.
    - Mobility comprises 72.5% and 50.3% of overall GHG reductions for conservative and ambitious demand scenarios, respectively, in the year 2045.
- Industrial and Power Generation GHG emissions are almost entirely eliminated when fossil fuels are replaced by clean renewable hydrogen as a fuel in combustion equipment. Hard-to-Electrify Industrial sectors benefit from clean

---

[91] SoCalGas's Demand Study projections were based on independently developed assumptions and analysis of potential hydrogen uptake in the SoCalGas service territory. The Demand Study was peer reviewed by experts at third parties, including National Renewable Energy Lab (NREL), South Coast Air Quality Management District (South Coast AQMD), University of California Los Angeles (UCLA), UC Irvine (UCI), and UC Davis (UCD). When looking at these projections holistically, the Demand Study's conclusions are near or within the range of recently released projections of hydrogen demand in California.

renewable hydrogen in reducing emissions from processes that are currently reliant on high-temperature operations and fossil fuels. The smaller percentage in overall reductions compared to mobility and power generation reflects the complex challenges and slower transition expected in these sectors.

- Power generation comprises 23.6% and 41.7% of overall GHG reductions for conservative and ambitious demand scenarios, respectively, in 2045.
- Industrial comprises 3.9% and 8.1% of overall GHG reductions for conservative and ambitious demand scenarios, respectively, in 2045.

Table 9
Annual Change in Direct GHG Emissions for Demand Scenarios (MT CO_2e/yr)

Category	Demand Scenario	2030	2035	2040	2045
End-Users	Conservative	-1,261,530	-4,864,767	-10,265,012	-16,731,269
	Moderate	-2,762,724	-7,948,981	-15,674,833	-24,958,279
	Ambitious	-5,729,290	-13,244,418	-23,490,552	-35,776,958
Infrastructure	Max - Conservative	1,966	7,807	16,765	28,512
	Max – Moderate	4,234	13,363	27,657	46,447
	Max – Ambitious	16,583	34,339	58,568	87,899
	Min - Conservative	0	0	0	0
	Min – Moderate	0	0	0	0
	Min – Ambitious	0	0	0	0
TOTAL	Conservative	-1,259,565	-4,856,960	-10,248,247	-16,702,756
	Moderate	-2,758,490	-7,935,593	-15,647,156	-24,911,832
	Ambitious	-5,712,707	-13,210,054	-23,431,964	-35,689,059

Table 9 presents a comprehensive view of the anticipated yearly change in GHG emissions across different scenarios, capturing the transformational impact of clean renewable hydrogen adoption by end-users within the SoCalGas territory by 2045. In the conservative demand scenario, end-user emissions reductions start at 1.3 million metric tons (MT) of CO2e per year in 2030 and expand to a reduction of 16.7 million MT CO2e by 2045. The moderate and ambitious scenarios show even more dramatic decreases, with the ambitious scenario projecting reductions of over 35.8 million MT CO2e annually by 2045. Conversely, infrastructure related GHG emissions represent a minimal increase in the overall emissions profile, peaking at just 0.29% of the magnitude of end-user reductions.

The overall GHG reductions shown conservatively apply the high-end (max values) of the infrastructure emission estimates that range from zero to 87,899 MT/year in 2045 for the ambitious demand scenario. The overall estimated GHG reductions range from 5.7 MMTYP CO_2e in 2030 to 35.7 MMTPY CO_2e by 2045.

The analysis shows the potential for GHG emission reductions, equating to the annual power usage of over 3.25 million homes for the conservative demand scenario and more than 6.96 million homes for the ambitious demand scenario, emphasizing the role of end-users in driving down GHG emissions through hydrogen use.

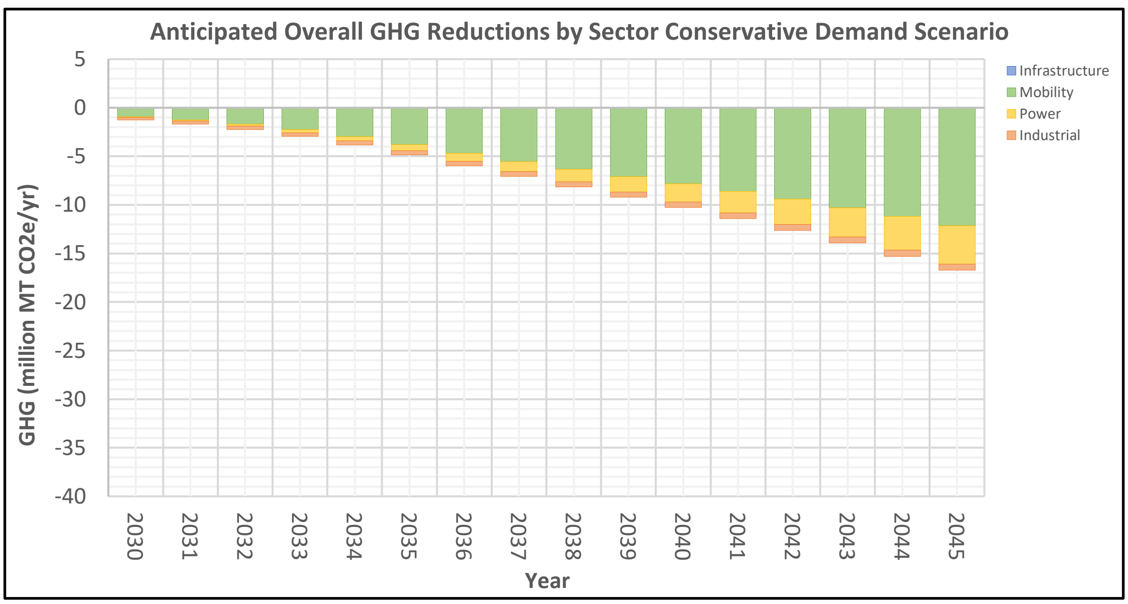

Figure 5A. Anticipated Overall GHG Reductions by Sector - Conservative Demand Scenario

Figure 5A depicts the anticipated GHG reductions by sector in the conservative demand scenario. It shows that the Mobility sector accounts for the largest share of reductions, making up 72.5% of the total decrease in emissions. This sector's change is depicted as the largest portion, underscoring the impact of replacing traditional vehicle fuels with hydrogen fuel cells. Power generation and industrial sectors follow, illustrating the transition from fossil fuels to clean hydrogen and their respective contributions to the total reduction in emissions. The clear delineation of contributions across sectors highlights the critical importance of sector-specific strategies in achieving GHG emission targets.

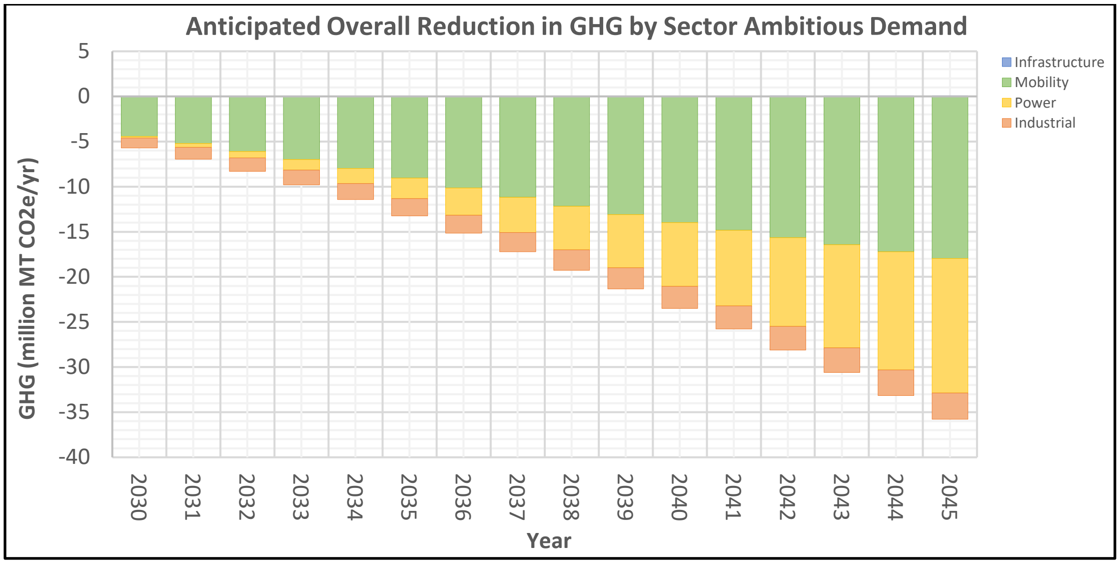

Figure 5B. Anticipated Overall GHG Reductions by Sector - Ambitious Demand Scenario

In Figure 5B, the reductions in GHG emissions are presented under the ambitious demand scenario, indicating a faster approach to hydrogen integration. The scale of reductions is more substantial compared to the conservative demand scenario, with Mobility again constituting the bulk of the decrease but at a relatively lower percentage, suggesting a broader distribution of clean hydrogen usage across sectors. The Power sector's contribution is markedly increased, consistent with the larger role of clean hydrogen in high-demand futures. The Industrial sector, while smaller in percentage, also shows a decrease in emissions, reaffirming the potential of hydrogen to transform even the most challenging sectors. The collective representation of sectors in this figure reflects a dynamic shift towards a low-carbon economy with substantial GHG emissions reductions.

7 ASSUMPTIONS AND RESULTS FOR ANGELES LINK THROUGHPUT SCENARIOS

Emission calculation results including assumptions are provided for the following categories that were evaluated for the Angeles Link Throughput Scenarios. The projected GHG emissions reductions totals for each end-user subsector were summed to estimate totals for each sector; and then totals for each sector were summed and added to anticipated GHG emissions associated with new infrastructure to estimate the overall annual GHG emissions reductions based upon the Angeles Link Throughput Scenarios and anticipated for each year 2030 to 2045.

- Infrastructure: production, storage, and transmission of hydrogen to end-users
- End-Users: mobility, power generation, and hard-to-electrify industrial sectors projected to use hydrogen

This document provides the results of the GHG study. Detailed emission calculations based on the Angeles Link Throughput Scenarios are provided in Appendix C.

7.1 INFRASTRUCTURE

The results for potential GHG emission increases associated with the new Angeles Link-related infrastructure based on the data for 2045 project that such are up to 0.17% and 0.25% the magnitude of end-user reductions for Angeles Link Low and High Throughput Scenarios, respectively.

7.1.1 Hydrogen Production (Third-Party)

Three equipment options were evaluated for hydrogen production to meet the definition of clean renewable hydrogen:

1. Electrolyzers powered by renewable electricity: zero GHG
2. Biomass gasification: zero GHG[92]
3. RNG SMR with hydrogen as combustion fuel for heater: Could include some GHG emissions in the form of trace amounts of N_2O.

Multiple scenarios were evaluated with varying contributions to total production by each of the three types of equipment listed above to estimate the range of potential GHG emissions. The range extends from zero GHG associated with 100% electrolysis and 100% biomass gasification scenarios to the potential for some GHG emissions for the 100% RNG SMR scenario. GHG emission estimates can be refined once further project details are developed, including assumptions regarding anticipated production processes and proportions of hydrogen intended to be produced from different methods have been

[92] The Study only considered biomass gasification that uses a process that is carbon neutral.

identified. Results are provided for the Low and High Throughout Scenarios in Table 10. Detailed information is available in the excel spreadsheets found in Appendix C.

Table 10
Potential Direct GHG Emissions from Hydrogen Production Based on Angeles Link Throughput Scenarios

Angeles Link Throughput Scenario	Emissions (MT CO2e/year)				
	2030	2035	2040	2045	Production Scenario
Low Min	0	0	0	0	100% Electrolysis or 100% Biomass Gasification
Low Max	301	1,194	2,564	4,361	100% SMR (Max Case)
High Min	0	0	0	0	100% Electrolysis or 100% Biomass Gasification
High Max	2,396	4,962	8,463	12,701	100% SMR (Max Case)

Table 10 depicts the estimated GHG emissions from hydrogen production related to the throughput scenarios. For both low and high throughput scenarios, the minimum potential emissions are zero, representing methods like electrolysis and biomass gasification. In contrast, the maximum emissions under the low throughput scenario rise from about 301 MT CO2e in 2030 to 4,361 MT CO2e by 2045 for 100% SMR. Similarly, under the high throughput scenario, maximum emissions increase from 2,396 MT CO2e to 12,701 MT CO2e within the same timeframe for the 100% SMR option.

7.1.2 Storage (Third-Party) and Transmission

Compressors will be needed for storage and transmission of hydrogen. Three options for types of compressors were evaluated.

1. Electric motor driven compressors (zero GHG emissions)
2. Clean renewable hydrogen fueled reciprocating engine driven compressors (some GHG emissions)
3. Clean renewable hydrogen fueled turbine driven compressors (some GHG emissions)

Emissions of GHG (as N_2O) from hydrogen fueled reciprocating engine driven compressors and from turbine driven compressors were conservatively estimated using equation 1.

*Fuel Throughput x Emissions Factor * GWP = GHG Emissions (equation 1)*

The first equation (equation 1) multiplies the quantity of clean renewable hydrogen by the N_2O emission factor assumed in this Study for hydrogen. The emissions for N_2O are then multiplied by the GWP as shown in Table 1 to determine GHG emissions in units of CO2e.

Two storage pressure scenarios were evaluated - a low pressure scenario at 290 psi and a high-pressure scenario at 2,900 psi. A total transmission distance of 450 miles was evaluated. These assumptions were made for this Study and additional information is available in the parallel Pipeline Sizing and Routing Study. GHG emission estimates can be refined once the types, sizes, and quantities of compressors have been further developed. Additionally, development of assumptions regarding aboveground and underground storage volumes and pressures will support refinement of potential GHG emission estimates for third-party storage. Results for storage and transmission for GHG emissions are provided in Tables 11 and 12, respectively. Detailed information is available in the excel spreadsheets found in Appendix C.

Table 11
Potential Direct GHG Emissions from Hydrogen Storage Based on Angeles Link Throughput Scenarios

Angeles Link Throughput Scenario	Emissions (MT CO_2e/yr)				Scenario	
	2030	2035	2040	2045	Storage Pressure	Power Source
Low Min	0	0	0	0	NA	Renewable Electricity
Low Max	64	253	543	923	2,900 psi	Turbine Engine
High Min	0	0	0	0	NA	Renewable Electricity
High Max	507	1,050	1,791	2,688	2,900 psi	Turbine Engine

Table 11 outlines the potential GHG emissions from hydrogen storage under different Angeles Link throughput scenarios. The table presents a range from zero emissions, which would occur when using renewable electricity for all storage pressures, to a maximum emission scenario where hydrogen is stored at high pressure (2,900 psi) using turbine engines. The maximum emissions for the low throughput scenario grow from about 64 MT CO2e in 2030 to 923 MT CO_2e by 2045. In the high throughput scenario, the projected maximum emissions are greater, starting at 507 MT CO2e in 2030 and reaching approximately 2,688 MT CO2e by 2045.

Table 12
Potential Direct GHG Emissions from Transmission Based on Angeles Link Throughput Scenarios

Angeles Link Throughput Scenario	Emissions (MT CO_2e/yr)				Scenario	
	2030	2035	2040	2045	Transmission Distance	Power Source
Low Min	0	0	0	0	NA	Renewable Electricity
Low Max	163	649	1,394	2,371	450 miles	NA
High Min	0	0	0	0	NA	Renewable Electricity
High Max	1,302	2,697	4,600	6,903	450 miles	NA

Table 12 presents the anticipated GHG emissions from the transmission of hydrogen, varying by Angeles Link throughput scenarios over a set distance of 450 miles. Similar to the hydrogen production and storage tables, the emissions for transmission are presented as ranging from zero—using renewable electricity—to a maximum calculated based on undefined sources (NA). For the low throughput scenario, maximum emissions estimates increase from about 163 MT CO2e in 2030 to 2,371 MT CO2e by 2045. The high throughput scenario starts with 1,302 MT CO2e in 2030 and climbs to 6,903 MT CO2e by 2045. These figures provide an insight into the anticipated GHG emissions associated with hydrogen transmission. Detailed information is available in the excel spreadsheets found in Appendix C.

7.2 END USERS

Consistent with the Decision, Angeles Link is intended to transport clean renewable hydrogen to the end users. The focus of the GHG emissions study was on three sectors of end-users: mobility, power generation, and hard to electrify industrial. The Throughput Scenarios estimated quantities of diesel and gasoline that may be displaced by hydrogen fuel cells in the mobility sector. The Throughput Scenarios also estimated quantities of natural gas that may be displaced by hydrogen fuel in the power generation and hard to electrify industrial sectors. The potential for leakage at end users is acknowledged but was not quantified as part of this Study.

7.2.1 Mobility

Summary of results for the anticipated GHG emission reductions associated with the Mobility sector based on the Low and High Throughput Scenarios for Angeles Link in 2045 are the following.

- Mobility is the largest end-user sector of GHG reductions at 72.5% and 50.3% of overall reductions for Low and High Throughput Scenarios, respectively. These reductions are due to hydrogen fuel cell substitution for fossil fuels nearly eliminating GHG emissions. The potential for leakage such as during refueling of vehicles is acknowledged but was not quantified as part of this study.
    - Low Throughput Scenario
        - On-Road Vehicles account for 93.9% of Mobility GHG reductions
            - Heavy Duty Vehicles are 58.5% of Mobility GHG reductions
        - Off-Road Vehicles account for 6.1% of Mobility GHG reductions
    - High Throughput Scenario
        - On-Road Vehicles account for 94.6% of Mobility GHG reductions
            - Heavy Duty Vehicles are 62.8% of Mobility GHG reductions
        - Off-Road Vehicles account for 4.4% of Mobility GHG reductions

On-Road Vehicles, Heavy Duty Vehicles, and Off-Road Vehicles have distinct roles in the mobility sector's GHG reductions, with on-road vehicles leading in both scenarios due to their higher contributions to emissions. The assumptions associated with the Mobility sector are primarily that diesel and gasoline fuel will be displaced, and vehicles would convert to hydrogen fuel cells with zero emissions. Emission factors for GHG from displaced diesel and gasoline fuel were developed using EMFAC data. The EMFAC model contains sufficient data to estimate CO_2, CH_4, and N_2O emissions for on-road mobile sources, and CO_2 emissions for off-road mobile sources. The EMFAC model does not include CH_4 and N_2O emissions data for off-road mobile vehicles. Research was conducted to estimate the most representative CH_4 and N_2O emissions factors for off-road mobile sources. Fuel consumption was weighted by subcategory of vehicle types. The same two equations previously mentioned were used to conduct the GHG calculations, and the hydrogen emissions value in equation 2 is zero.

*Fuel Throughput x Emissions Factor * GWP = GHG Emissions (equation 1)*

GHG Emission Reductions = Fossil Fuel GHG Emissions – Hydrogen GHG Emissions (equation 2)

The first equation (equation 1) multiplies the quantity of fuel by the GHG emission factor specific to the fuel for each GHG pollutant. These pollutants are CO_2, CH_4, and N_2O for combustion of fossil fuels and N_2O for combustion of hydrogen. Each GHG has a specific fuel dependent emission factor and a unique GWP as shown in Table 1. The emissions for each of CO_2, CH_4, and N_2O are multiplied by their respective GWP and then summed to obtain the total GHG emissions in units of CO2e.

The second equation (equation 2) calculates the GHG emission reductions in CO2e by subtracting the GHG emissions for hydrogen (either for N_2O from combustion of hydrogen or zero for hydrogen fuel cells) from the GHG emissions for combustion of displaced fossil fuels. The GHG emissions for combustion of hydrogen and for combustion of fossil fuels are both derived from equation 1.

The total emissions were calculated by summing totals for each equipment type and are shown in Table 13. Figures 6A and 6B provide graphs for the Low and High Throughput Scenarios, respectively below. The GHG reductions estimated for the Low Throughput Scenario in 2045 are equivalent to 775,000 gasoline passenger vehicles driven for one year per EPA Calculator. The GHG reductions estimated for the High Throughput Scenario in 2045 are equivalent to about 1,085,300 gasoline passenger vehicles driven for one year per EPA Calculator. Detailed information is available in the excel spreadsheets found in Appendix C.

Table 13
Mobility Direct GHG Emission Reductions Associated with Angeles Link Throughput Scenarios
(million MT CO_2e/yr)

Scenario	2030	2035	2040	2045
Low	0.25	1.02	2.10	3.26
High	1.12	2.29	3.54	4.56

Table 13 presents the GHG emission reductions within the mobility sector as a result of the Angeles Link Throughput Scenarios from 2030 to 2045. In the Low Throughput Scenario, the reductions begin at 0.25 million MT CO2e in 2030 and increase over the years to reach 3.26 million MT CO2e by 2045. This indicates a steady increase in the use of hydrogen as a fuel, replacing traditional carbon-intensive fuels in vehicles. The High Throughput Scenario predicts reductions starting with 1.12 million MT CO2e in reductions in 2030 and expanding to 4.56 million MT CO2e by 2045. These substantial figures suggest aggressive displacement of fossil fuels with hydrogen fuel cells, reflecting the potential for large GHG reductions in the transportation sector with the adoption of clean renewable hydrogen technology.

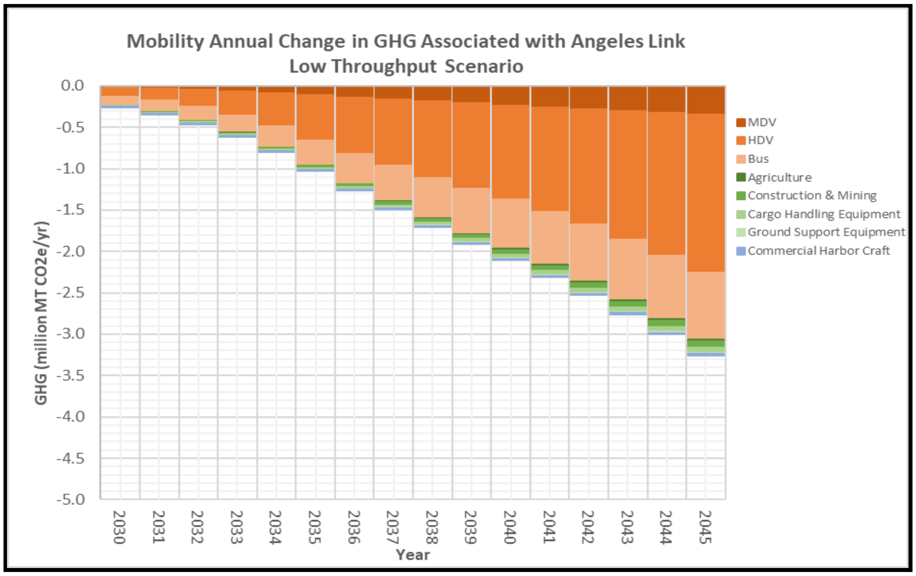

Figure 6A. Mobility Annual Change in GHG for Angeles Link - Low Throughput Scenario

Figure 6A illustrates the projected yearly reductions in GHG emissions from various subsectors of mobility, such as Medium Duty Vehicles (MDV), Heavy Duty Vehicles (HDV), Buses, and Agriculture from 2030 to 2045. The dominant segments, representing MDVs, indicate that this subsector is expected to contribute the largest share to GHG reductions, particularly as we approach 2045. The figure reflects an increased rate of emission reductions over time, aligning with the anticipated broader adoption of clean hydrogen fuel cells in these vehicle categories.

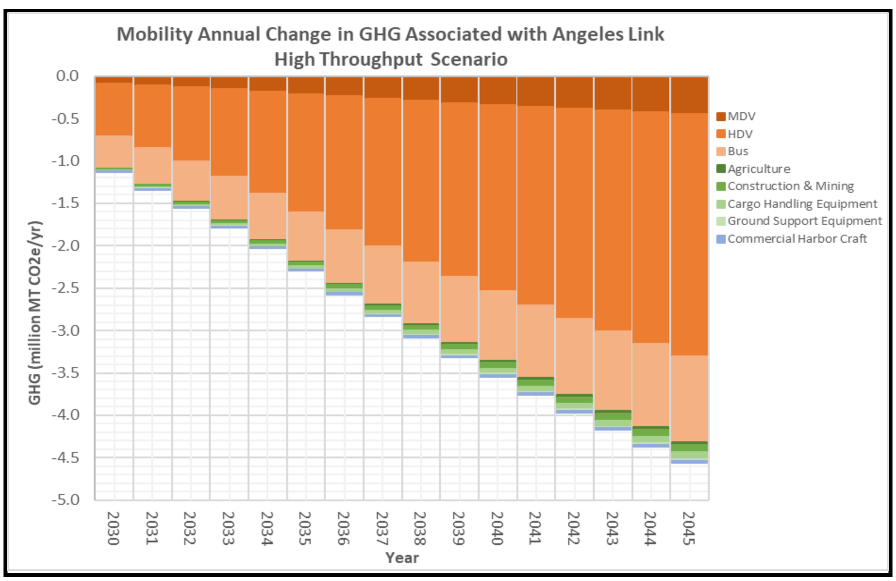

Figure 6B. Mobility Annual Change in GHG for Angeles Link - High Throughput Scenario

In Figure 6B, we see a similar trend of GHG reduction across the mobility sector, albeit with smaller absolute numbers compared to the high throughput scenario. This chart shows that even with a more conservative adoption of hydrogen fuel cell technology, emission reductions are projected, especially from MDVs and buses, which make up the majority of the reductions. The gradual increase in the size of the colored segments over the years suggests the growing impact of transitioning to hydrogen-powered transportation within the lower demand framework. The graph indicates that by 2045, the shift to hydrogen in mobility could yield emission reductions comparable to taking a large number of traditional vehicles off the road.

7.2.2 Power Generation

Results for anticipated GHG emissions reductions based on the Angeles Link Low and High Throughout Scenarios in 2045 are that the Power Generation sector accounts for 24% and 42% of overall GHG emissions reductions, respectively. The assumptions that were applied to develop the GHG emissions calculations include that hydrogen will displace natural gas as a fuel with increasing amounts over time (from 2030 to 2045). The potential for leakage at power generation end users such as when hydrogen is transferred from onsite storage or pipelines to onsite hydrogen combustion equipment is acknowledged but was not quantified as part of this study.

This Study is focused on estimated GHG reductions anticipated to be associated with use of hydrogen as a fuel in the power generation sector relating to the development of Angeles Link. At the time of this study report, there is not sufficient detailed project information to estimate the quantity of electricity that is anticipated to be produced using 100% clean renewable hydrogen as a fuel to electric generating equipment as the future annual average utilization or the capacity factor for thermal power plant generation is not known. For each emission source type identified, calculations to estimate GHG emissions were prepared using the same two equations previously mentioned.

*Fuel Throughput x Emissions Factor * GWP = GHG Emissions (equation 1)*

GHG Emission Reductions = Fossil Fuel GHG Emissions – Hydrogen GHG Emissions (equation 2)

The first equation (equation 1) multiplies the quantity of fuel by the GHG emission factor specific to the fuel for each GHG pollutant. These pollutants are CO_2, CH_4, and N_2O for combustion of fossil fuels and N_2O for combustion of hydrogen. Each GHG has a specific fuel dependent emission factor and a unique GWP as shown in Table 1. The emissions for each of CO2, CH_4, and N_2O are multiplied by their respective GWP and then summed to obtain the total GHG emissions in units of CO2e.

The second equation (equation 2) calculates the GHG emission reductions in CO2e by subtracting the GHG emissions for hydrogen (either for N_2O from combustion of hydrogen or zero for hydrogen fuel cells) from the GHG emissions for combustion of displaced fossil fuels. The GHG emissions for combustion of hydrogen and for combustion of fossil fuels are both derived from equation 1.

As previously mentioned, for combustion of clean renewable hydrogen with GHG comprised entirely of N_2O, since the GWP 20 and GWP 100 for N_2O are both 273, the expected impacts in both short term and long term should be similar.

The total emissions were calculated by summing totals for each equipment type and are shown in Table 14. Figures 7A and 7B provide graphs for the Angeles Link Low and High Throughput Scenarios, respectively below. The GHG reductions estimated for the Low Throughput Scenario in 2045 are equivalent to 206,101 homes' electricity use for one year per EPA Calculator. The GHG reductions estimated for the High Throughput Scenario in 2045 are equivalent to 735,486 homes' electricity use for one year per EPA Calculator. Detailed information is available in the excel spreadsheets found in Appendix C.

Table 14
Power Generation GHG Combustion Emission Reductions Associated with Angeles Link Throughput Scenarios (million MT CO2e/yr)

Throughput Scenario	2030	2035	2040	2045
Low	0.012	0.16	0.50	1.06
High	0.041	0.58	1.79	3.78

Table 14 offers a detailed account of the projected GHG emission reductions within the power generation sector under the Angeles Link Throughput Scenarios. For the Low Throughput Scenario, the table shows a ten-fold increase in GHG reductions over time, starting at 0.12 million MT CO2e in 2030 and increasing to 1.06 million MT CO2e by 2045. In the High Throughput Scenario, the GHG emission reductions begin at 0.41 million MT CO2e in 2030 and ramping up to 3.78 million MT CO2e by 2045.

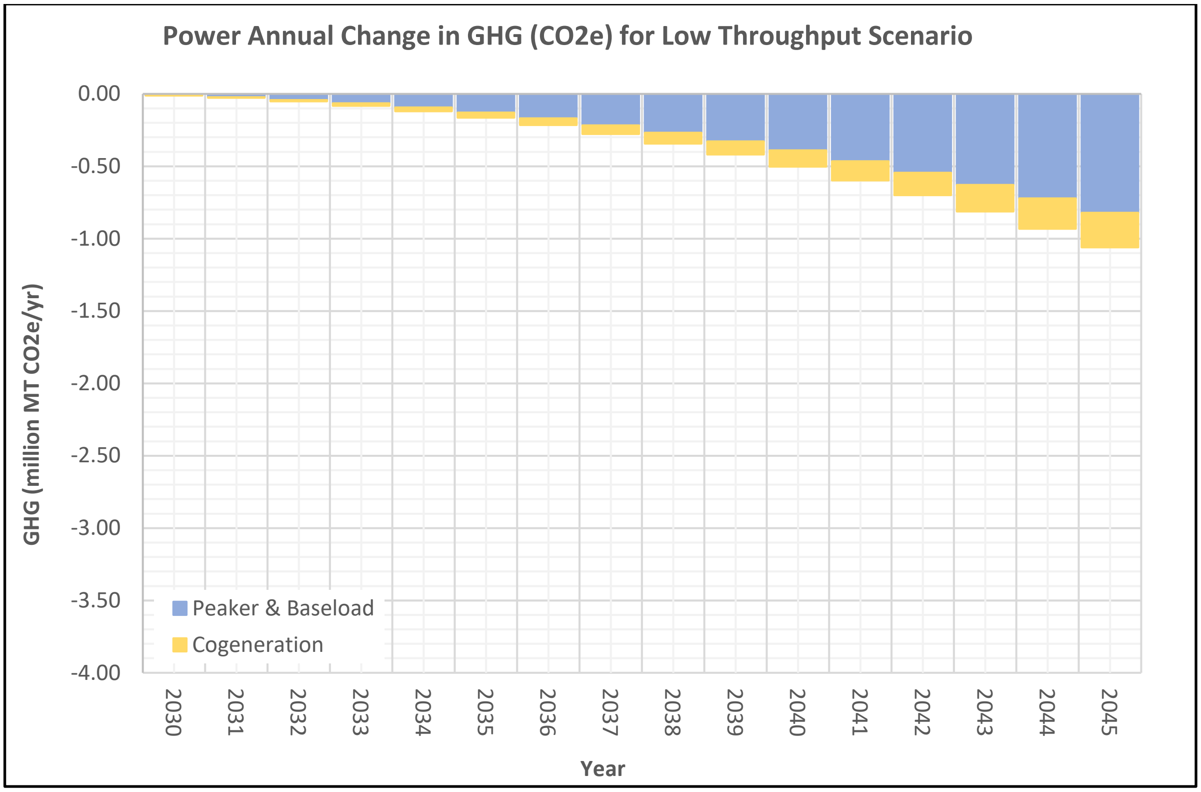

Figure 7A. Power Annual Change in GHG for Angeles Link - Low Throughput Scenario

Figure 7A displays the expected annual reductions in GHG emissions for the Power sector from 2030 to 2045. The stacked bars depict a year-over-year decrease in GHG emissions. This visualization highlights the large-scale impact of transitioning to hydrogen-fueled power generation, with cogeneration units also showing notable reductions. The clear decline in emissions over the years signifies the increasing role of clean hydrogen in achieving emissions targets within the Power sector.

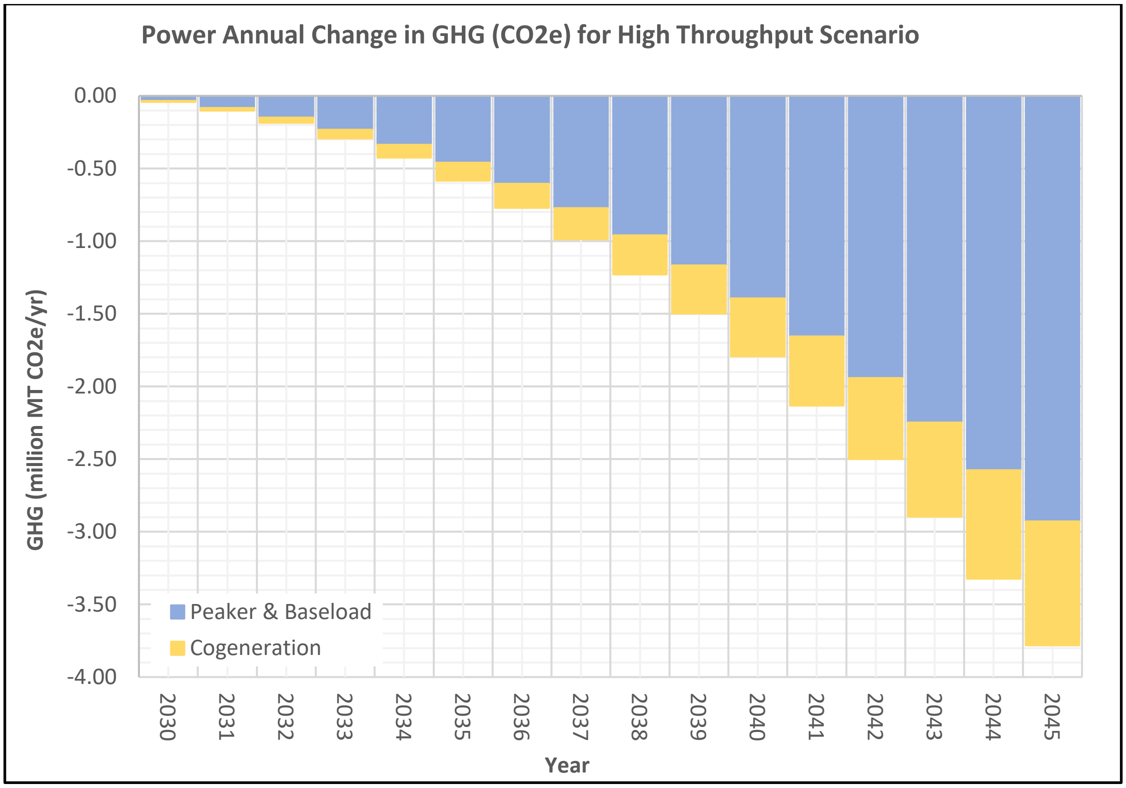

Figure 7B. Power Annual Change in GHG for Angeles Link - High Throughput Scenario

In Figure 7B, the estimated GHG reductions are showcased for the power sector with a less aggressive but steady transition towards hydrogen. The peaker baseload and cogeneration are again represented, showing a consistent trend of decreasing emissions over time. The color coding of the bars clearly shows the contributions from each type of generation unit to the overall reduction, with a trajectory pointing towards an environmental benefit by 2045. The chart underlines the potential of hydrogen to substantially lower GHG emissions even with lower adoption rates, indicating the effectiveness of hydrogen as a clean alternative to fossil fuels in Power generation.

7.2.3 Hard to Electrify Industrial

The results for the anticipated GHG emissions reductions associated with the Industrial sector based on the Angeles Link Low and High Throughput Scenario data in 2045 are that the Industrial sector accounts for 4% and 8% of overall GHG emissions reductions, respectively. The assumptions that were applied to develop the GHG emissions calculations include that hydrogen will displace natural gas as a fuel with increasing amounts over time (from 2030 to 2045). It should be noted that consistent with the Decision, Angeles Link is intended to transport clean renewable hydrogen, and any analysis of hydrogen blending refers strictly to “behind-the-meter” operations, not within SoCalGas control. This Study does not dictate if end users will blend hydrogen with natural gas and makes assumptions regarding adoption rates based on currently available information regarding equipment and the anticipated evolution of adoption over time. Since only 100% clean renewable hydrogen will be delivered, to estimate GHG reductions at end users, assumptions regarding hydrogen adoption rates were made as shown in Tables 2A and 2B. The estimated emissions are based on these assumptions.

The potential for leakage at hard to electrify industrial end users such as when hydrogen is transferred from onsite storage or distribution to onsite hydrogen combustion equipment is acknowledged but was not quantified as part of this study.

For each emission source type identified, calculations to estimate emissions were prepared using the same two equations previously mentioned.

*Fuel Throughput x Emissions Factor * GWP = GHG Emissions (equation 1)*

GHG Emission Reductions = Fossil Fuel GHG Emissions – Hydrogen GHG Emissions (equation 2)

The first equation (equation 1) multiplies the quantity of fuel by the GHG emission factor specific to the fuel for each GHG pollutant. These pollutants are CO_2, CH_4, and N_2O for combustion of fossil fuels and N_2O for combustion of hydrogen. Each GHG has a specific fuel dependent emission factor and a unique GWP as shown in Table 1. The emissions for each of CO_2, CH_4, and N_2O are multiplied by their respective GWP and then summed to obtain the total GHG emissions in units of CO2e.

The second equation (equation 2) calculates the GHG emission reductions in CO2e by subtracting the GHG emissions for hydrogen (either for N_2O from combustion of hydrogen or zero for hydrogen fuel cells) from the GHG emissions for combustion of displaced fossil fuels. The GHG emissions for combustion of hydrogen and for combustion of fossil fuels are both derived from equation 1.

As previously noted, for combustion of clean renewable hydrogen with GHG emissions comprised entirely of N_2O, since the GWP 20 and GWP 100 for N_2O are both 273, the expected impacts in both short term and long term should be similar.

Total emissions were calculated by summing totals for each equipment type and are shown in Table 15. Figures 8A and 8B provide graphs for the Angeles Link Low and High Throughput Scenarios, respectively below. The GHG emissions reductions predicted for the Low Throughput Scenario in 2045 are equivalent to about 35,500 homes’ electricity use for one year per EPA Calculator. The GHG emissions reductions predicted for the High Throughput Scenario in 2045 are equivalent to about 144,000 homes’ electricity use for one year per EPA Calculator. Detailed information is available in the excel spreadsheets found in Appendix C.

Table 15 Hard-to-Electrify Industrial GHG Combustion Emission Reductions Associated with Angeles Link Throughput Scenarios (million MT CO2e/yr)				
Throughput Scenario	**2030**	**2035**	**2040**	**2045**
Low	0.075	0.12	0.15	0.17
High	0.29	0.48	0.62	0.73

Table 15 quantifies the GHG emission reductions within the industrial sector influenced by the Angeles Link project under Low and High Throughput Scenarios. Starting in 2030, the Low Scenario estimates a reduction of 0.75 million MT CO2e, with a steady increase over time, reaching 0.18 million MT CO2e by 2045. The High Scenario projects more substantial reductions beginning at 0.29 million MT CO2e in 2030 and culminating at 0.73 million MT CO2e in 2045.

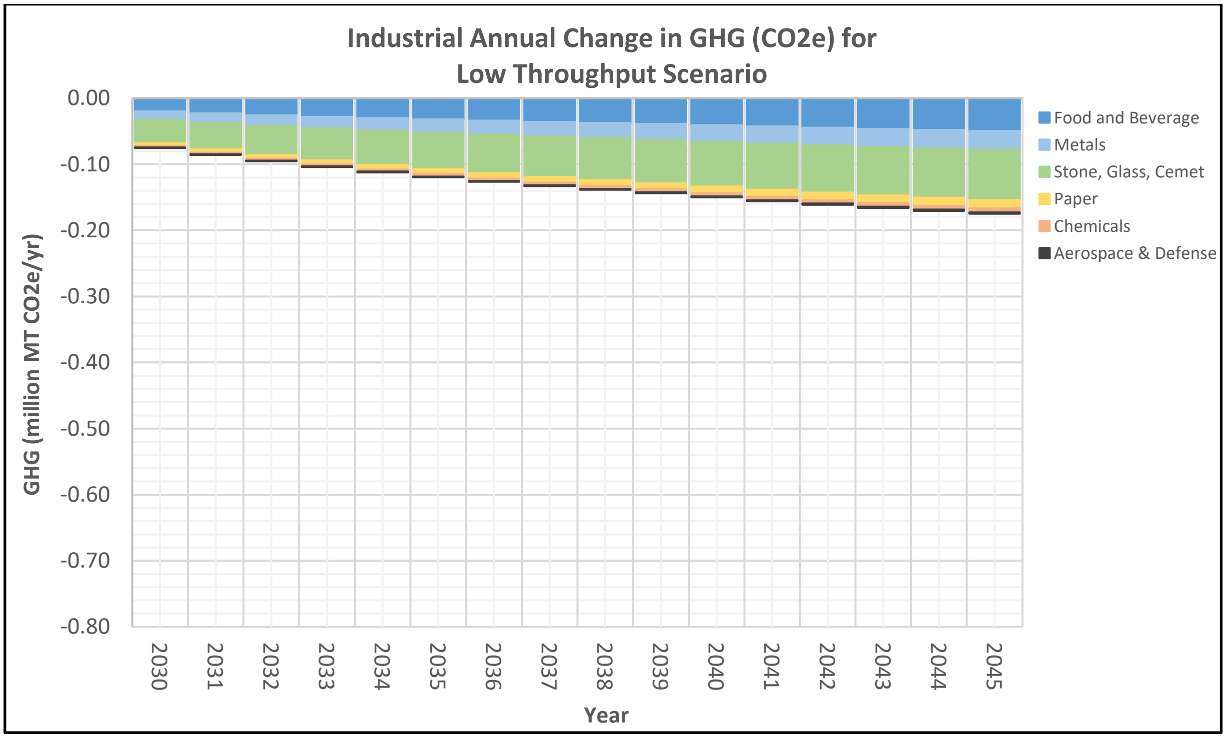

Figure 8A. Industrial Annual Change in GHG for Angeles Link - Low Throughput Scenario

Figure 8A depicts yearly reductions in GHG emissions across various industrial subsectors from 2030 to 2045. The largest decreases are seen in the food and beverage, and the stone/glass/cement sectors, shown by the deepest layers in the chart. As years progress, GHG emissions continue to fall, reflecting the increased adoption of hydrogen as a clean fuel alternative to natural gas, particularly in energy-intensive industries. By 2045, the emissions reduction is most pronounced, demonstrating the cumulative effect of the transition to hydrogen in high-demand scenarios.

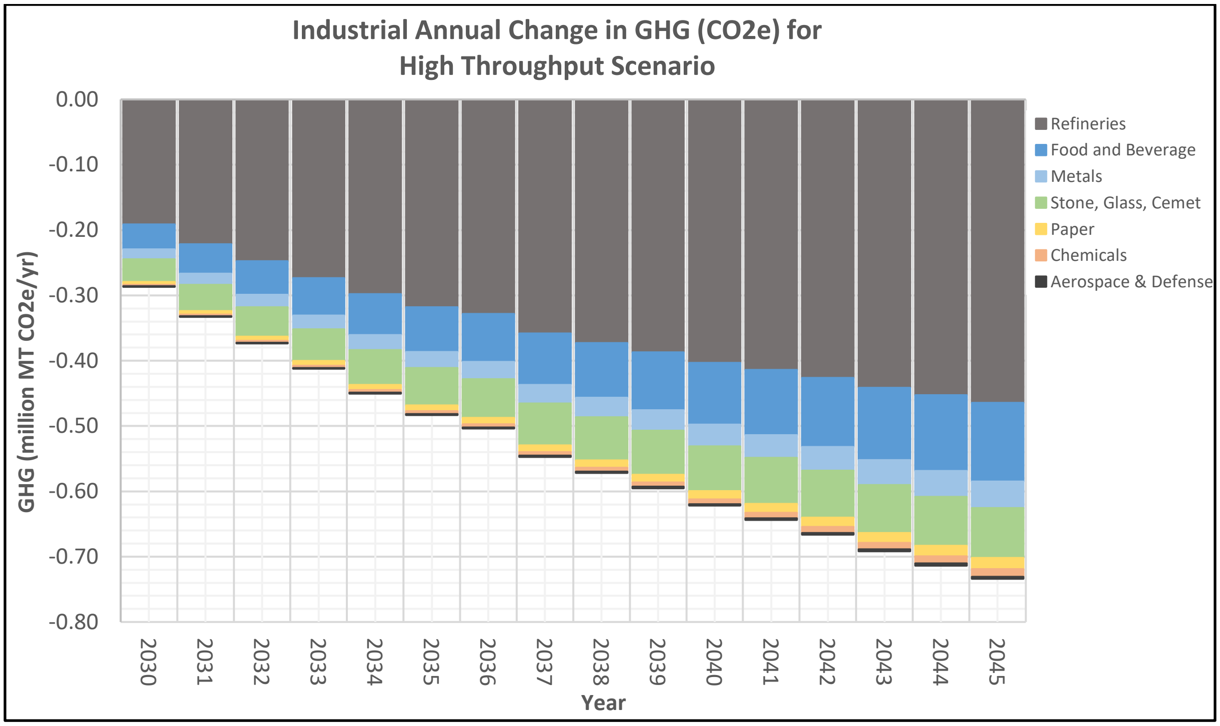

Figure 8B. Industrial Annual Change in GHG for Angeles Link - High Throughput Scenario

Figure 8B illustrates a conservative yet steady decline in GHG emissions within the industrial sector over the same period. In this scenario, refineries, food and beverage, and the stone/glass/cement sectors are also leading contributors to GHG reductions. Although the overall decrease in emissions is less aggressive than in the high throughput scenario, the continued year-over-year reductions indicate that even with a lower rate of hydrogen adoption, the industrial sector can achieve meaningful emissions reductions.

8 OVERALL RESULTS FOR ANGELES LINK THROUGHPUT SCENARIOS

Anticipated potential minor GHG emissions associated with new hydrogen infrastructure were added to the potential large anticipated GHG emissions reductions associated with potential end users of hydrogen as defined by the Demand Study. The total GHG emissions reductions projected for the Low Throughput Scenario in 2045 for end-users are equivalent to more than 874,000 homes' electricity use for one year per EPA Calculator. The total GHG emissions reductions predicted for the High Throughput Scenario in 2045 for end-users are equivalent to more than 1,760,000 homes' electricity use for one year per EPA Calculator. The results are provided in Table 16 and in Figures 9A and 9B below. Detailed information is available in the excel spreadsheets found in Appendix C.

In summary:

- Projected about 4.5 and 9 million metric tons of CO2e per year removed from SoCalGas territory geographic area by end users by 2045 in Angeles Link Low and High Throughput Scenarios.
- Projected new infrastructure GHG emissions are smaller than end-user reductions.
    - The highest potential infrastructure GHG emissions estimated are 0.17% and 0.25% the magnitude of overall end-user reductions for Angeles Link Low and High throughput scenarios, respectively, in 2045.
- Mobility GHG emissions are almost entirely eliminated with hydrogen substitution when fossil fuels are replaced with hydrogen fuel cells.
    - Mobility comprises 72.5% and 50.3% of overall GHG reductions for Angeles Link Low and High throughput scenarios, respectively, in 2045.
- Industrial and Power Generation GHG emissions are almost entirely eliminated when fossil fuels are replaced by hydrogen as a fuel in combustion equipment.
    - Power generation comprises 23.6% and 41.7% of overall GHG emissions reductions for Angeles Link Low and High throughput scenarios, respectively, in 2045.
    - Industrial comprises 3.9% and 8.1% of overall GHG emissions reductions for Angeles Link Low and High Throughput Scenarios, respectively, in 2045.

Table 16 **Annual Change in GHG Emissions for Angeles Link Throughput Scenarios (MT CO_2e/yr)**					
Category	**Through-put Scenario**	**2030**	**2035**	**2040**	**2045**
End-Users	Low	-338,689	-1,306,066	-2,755,894	-4,491,919
	Medium	-859,849	-2,473,978	-4,878,512	-7,767,819
	High	-1,453,026	-3,358,957	-5,957,517	-9,073,521
Infrastructure	Max - Low	528	2,096	4,501	7,655
	Max – Medium	1,318	4,159	8,608	14,456
	Max - High	4,206	8,709	14,854	22,292
	Min – Low	0	0	0	0
	Min - Medium	0	0	0	0
	Min - High	0	0	0	0
Total	Low	-338,161	-1,303,970	-2,751,393	-4,484,264
	Medium	-858,531	-2,469,812	-4,869,898	-7,753,363
	High	-1,448,820	-3,350,248	-5,942,663	-9,051,228

Table 16 reflects the changes in GHG emissions due to the Angeles Link project, which indicate a decline in emissions from end-users, particularly in the high throughput scenario with more than 9 million MT CO2e reduction by 2045. The overall GHG reductions shown conservatively apply the high-end (max value) of the infrastructure emission estimates that range from zero to 22,292 MT/year in 2045 for the high throughput scenario. These figures represent a shift toward cleaner energy and indicate a major potential for emissions reduction through clean renewable hydrogen adoption. Infrastructure-related emissions, while present, are minimal compared to the gains from end-user reductions.

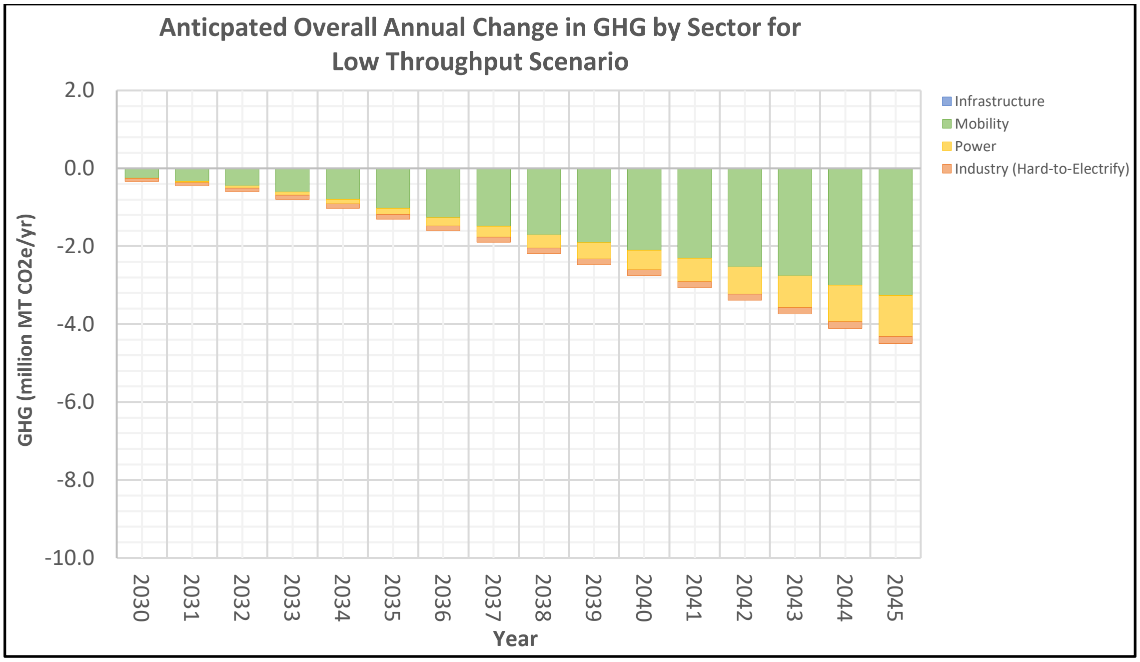

Figure 9A. Annual Change in GHG for Angeles Link - Low Throughput Scenario

In Figure 9A featuring the High Throughput Scenario, the stacked bar chart demonstrates a substantial decline in GHG emissions across all sectors, with the Mobility sector leading the reductions, followed by Power, and with Industry having the least, yet still notable GHG emission reductions. This visualizes a strategic and impactful cut in emissions through hydrogen adoption, especially in the Mobility sector.

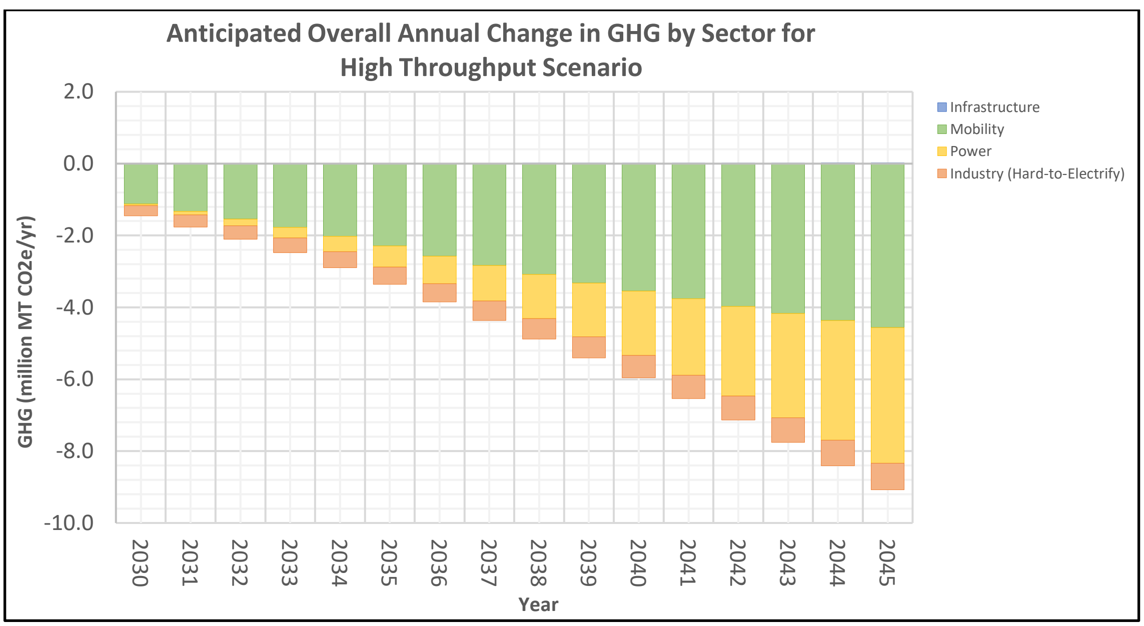

Figure 9B. Annual Change in GHG for Angeles Link - Low Throughput Scenario

In Figure 9B, for the Low Throughput Scenario, the trend is similar but with smaller reductions. Mobility still shows the most considerable decline, underscoring the role of cleaner transportation methods in reducing overall emissions. The consistent year-over-year decrease in all sectors reaffirms the value of even modest shifts toward clean renewable hydrogen for an environmental benefit.

9 HYDROGEN LEAKAGE IMPACT TO GHG REDUCTIONS

This Study broadens its scope to address concerns raised by stakeholders regarding hydrogen leakage, which represents a risk factor that could reduce a small percentage of the overall expected GHG reductions projected for Angeles Link. Addressing both direct and indirect GHG emissions, as raised by stakeholders, is essential for accurately assessing hydrogen's overall effectiveness as a means to achieve GHG reductions.

9.1 HYDROGEN AS INDIRECT GHG EMISSIONS

As outlined earlier in this document, this GHG report specifically estimates potential direct emissions of greenhouse gases such as CO_2, CH_4, and N_2O that can occur during fossil fuel or hydrogen combustion. It is important to note that hydrogen is not classified as a direct greenhouse gas by leading environmental organizations and governing bodies, including CARB, EPA, or the IPCC, due to the absence of globally recognized warming potentials. The research on global warming potential of hydrogen is evolving and there is not yet consensus among academic, regulatory, and climate organizations on the extent of the global warming impact of hydrogen. However, some analytical studies using atmospheric chemistry models estimate that hydrogen, if emitted to the atmosphere, will have an indirect global warming effect.[93]

Similar to methane, hydrogen's climate impacts are short-lived, with near-term climate change impacts from hydrogen expected to be 3 to 8 times higher than long-term impacts. Additionally, hydrogen's indirect impact on methane in the atmosphere results in a longer atmospheric lifetime for methane which could result in climate effects for about 10 years longer.[94]

Hydrogen's global warming impact may be caused by increasing methane residence time in the atmosphere, increasing production of tropospheric ozone (O_3) and altering stratospheric O_3, increasing the production of stratospheric water vapor, and changing the production of some aerosols.[95] These impacts are largely driven by the reaction of hydrogen and OH to form H_2O and H. OH is an atmospheric sink for methane and other atmospheric compounds.

Hydrogen combustion primarily results in the production of water vapor and very small amounts of N_2O may indirectly result from the nitrogen present in the combustion air at

[93] Bertagni, M.B., Pacala, S.W., Paulot, F. et al., 2022, Risk of the hydrogen economy for atmospheric methane. Nat Commun 13, 7706, https://doi.org/10.1038/s41467-022-35419-7

[94] Ocko, Ilissa and Hamburg, Steven, 2022, Climate consequences of hydrogen emissions. Atmospheric Chemistry and Physics, 2022. https://acp.copernicus.org/articles/22/9349/2022/

[95] Bertagni, M.B., et. al., 2022, Ibid.

specific temperatures. While water vapor is a greenhouse gas due to its ability to trap heat in the atmosphere, hydrogen combustion does not directly emit carbon-based greenhouse gases like CO_2 or CH_4, because hydrogen lacks carbon content. Therefore, the climate-related concerns associated with hydrogen primarily stem from its indirect effects rather than direct emissions. Key indirect effects of hydrogen combustion include:

- **Hydroxyl Radical Reduction:** Hydrogen can lower the concentration of hydroxyl radicals (OH) in the atmosphere. These radicals play a crucial role in breaking down methane, a greenhouse gas. When the levels of hydroxyl radicals are reduced, methane's atmospheric lifetime increases, which in turn amplifies its warming effect on the climate.
- **Ozone Formation:** When hydrogen is emitted, it can react with other compounds in the atmosphere under the influence of sunlight, leading to the formation of tropospheric ozone. This substance is not only a potent greenhouse gas but also a harmful air pollutant, contributing further to climate change.
- **Water Vapor Impact:** The oxidation of hydrogen leads to an increase in stratospheric water vapor, which can intensify the greenhouse effect. However, the impact of this increase is highly variable and complex to model accurately due to the intricate dynamics of the atmosphere.

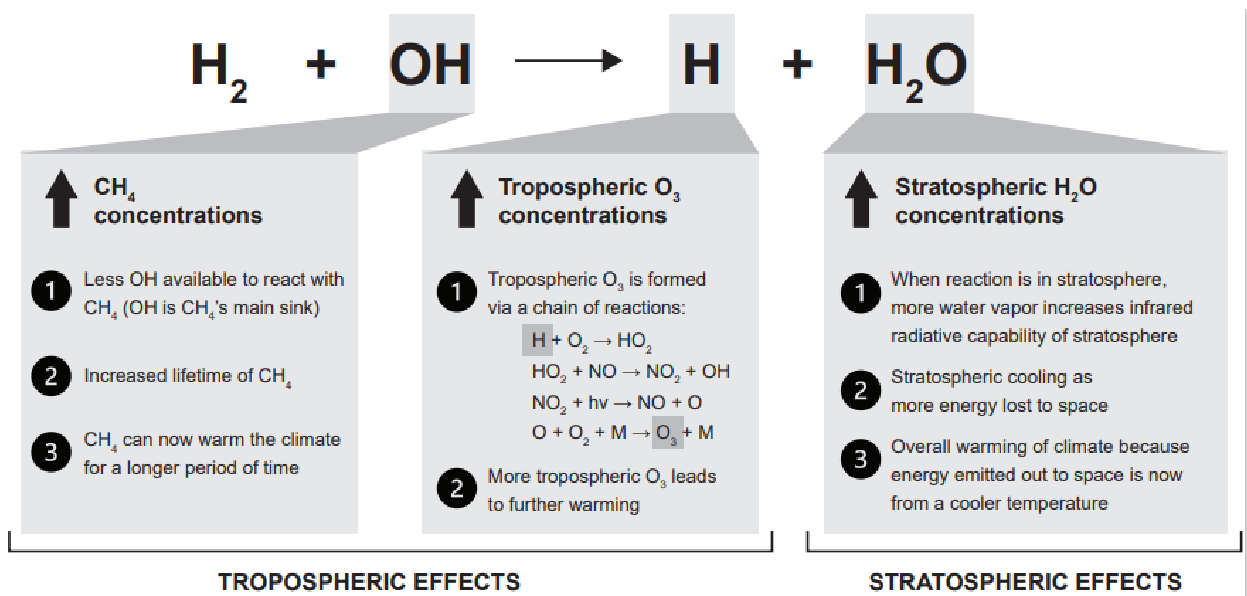

Figure 10. Estimated tropospheric and stratospheric effects of hydrogen

As shown in Figure 10,[96] scientific literature has identified potential climate impact considerations: 1) reduction in available hydroxyl radicals to react with methane, potentially prolonging methane's lifetime in the atmosphere; 2) increased tropospheric concentrations of ozone; and 3) increased concentrations of water vapor.

Research on hydrogen's global warming potential has evolved, with key findings consolidated in recent studies.[97] [98] Derwent's March 2023 article in the International Journal of Hydrogen Energy standardized earlier research, narrowing hydrogen's GWP to 7.1 to 9.3 over 100 years.[99] In contrast, Sand et al.'s June 2023 study, using five atmospheric chemistry models, proposed a GWP of 11.6 ± 2.8, focusing on emissions and potential infrastructure leakages.[100] This study highlighted the higher GWPs projected over shorter, 20-year horizons.[101] Notably, green hydrogen[102] could reduce GWPs by over 95% compared to fossil fuels over 20 to 100 years, based on leakage rates of 1 to 3%.[103] The primary uncertainties in developing a GWP for hydrogen continue to be the lack of data around the removal rate of atmospheric hydrogen by soil and potential future changes in atmospheric concentrations of other GHG such as methane.[104]

Table 17 presents a range of GWP values for hydrogen from various studies. These values can be used for developing effective GHG emission rates for hydrogen leakage as CO_2e.

- GWP100 Range of Estimates: This column lists the GWP for a 100-year time horizon, which is the standard measure used to compare the impacts of different GHGs. The "+/-" values indicate the uncertainty or range in these estimates.
- GWP20 Range of Estimates: This column provides GWP values for a 20-year time horizon, which highlights the short-term climate impact of the gases. Not all studies provide a 20-year GWP.

Table 17
Summary of GWP 20 and GWP 100 Estimates for Hydrogen

GWP100 Range of Estimates	GWP20 Range of Estimates	Date of Article	Article Authors

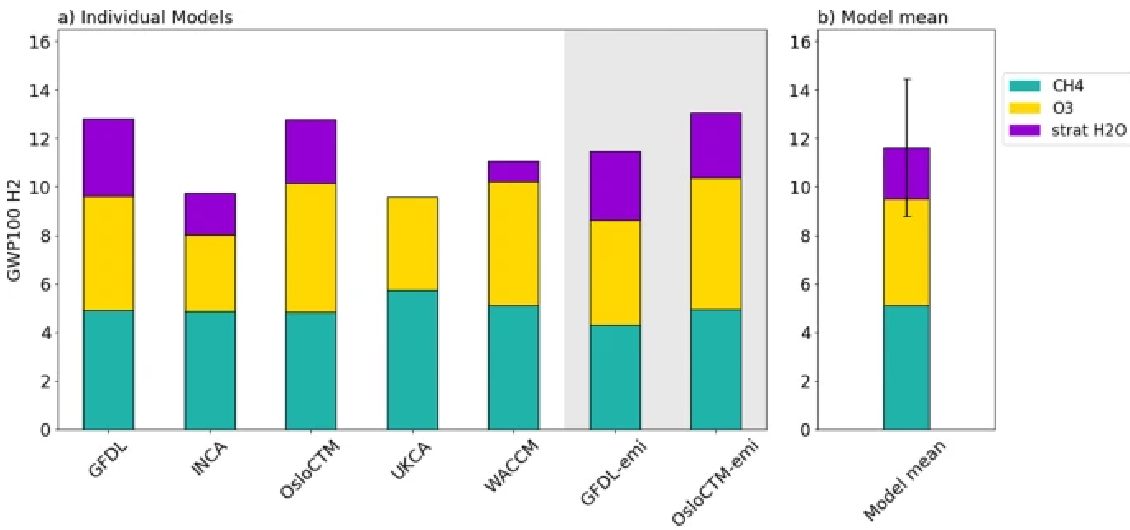
Understanding Multi-model Assessments of the Global Warming Potential of Hydrogen

To demonstrate that a number of data sources are typically evaluated to develop the values shown in Table 17 above, one row was selected (highlighted) and a deep-dive into the data was performed. For the row with the information from M. Sand et al. in June 2023[105], the authors evaluated the following information to develop the result in the study which estimates hydrogen's GWP100 to be 11.6, with a standard deviation of ±2.8 as shown in Table 17 above.

[105] Sand, M., et. al., 2023, Ibid.



GFDL Geophysical Fluid Dynamics Laboratory Model

The **GFDL** model operates with a resolution of approximately 100 km and 49 vertical levels. This model conducts experiments focused on meteorological aspects with a set of experiments that involve a control run with fixed H2 and CH4 concentrations, and several scenarios with different levels of increased H2 and CH4 concentrations. It uses its own meteorology for simulations which are conducted over a period of 20 years, focusing on atmospheric dynamics and climate processes.

The **GFDL-emi** is a variant with a specific focus on emission scenarios. It retains the same resolution and vertical levels as the GFDL model but explores the impacts of increased H2 emissions (200 Tg yr−1) along with a significant increase in CH4 concentrations. This model's experiments span 50 years, making it particularly valuable for studying long-term climatic effects of emission changes.

OSLOCTM Oslo Chemical Transport Model

OsloCTM features a resolution of roughly 2.25° x 2.25° with 60 vertical levels and conducts experiments under fixed H2 concentrations, along with increased H2 and CH4 scenarios. This model, using ECMWF OpenIFS 3 hr forecast data for meteorology, covers 20 years, **focusing** on the transport and transformation of chemical species in the atmosphere.

The **OsloCTM-emi** similarly maintains the same resolution and vertical levels and includes a scenario with increased H2 emissions (14 Tg yr−1). Its experiments also focus on the interaction between these emissions and atmospheric chemistry, using the same meteorological data and spanning 25 years.

INCA Interactive Chemistry and Aerosols

The **INCA** model utilizes a resolution of 2.5° × 1.25° with 39 vertical levels. It focuses on interactive chemistry, conducting experiments on present-day control scenarios with fixed H2 concentrations and simulations examining increases in H2 and CH4. INCA uses ECMWF OpenIFS 3 hr forecast data for meteorology and spans 20 years in simulation, emphasizing atmospheric chemistry and climate interactions.

UKCA United Kingdom Chemistry and Aerosols

The **UKCA** model operates with a resolution of 1.250° × 1.875° and 85 vertical levels. It performs experiments involving fixed H2 concentrations and a 10% increase in H2 and CH4 concentrations. The UKCA uses its own meteorology and runs simulations for 18 years, focusing on the study of atmospheric chemistry, aerosols, and their impact on climate.

WACCM Whole Atmosphere Community Climate Model

WACCM6 utilizes a resolution of 1.875° × 2.5° with 88 vertical levels and conducts experiments focusing on fixed H2 concentrations, and a 10% increase in both H2 and CH4 concentrations. It uses its own meteorological data and its simulation covers 20 years, integrating atmospheric chemistry with climate dynamics to model the whole atmosphere comprehensively.

The article "Climate Impacts of Hydrogen and Methane Emissions Can Considerably Reduce the Climate Benefits across Key Hydrogen Use Cases and Time Scales,"[106] published recently in Environmental Science & Technology, explores the complexities surrounding the assessment of climate impacts associated with hydrogen energy systems. The article discusses the global warming potential of hydrogen over shorter periods, driven by its indirect effects on methane, tropospheric ozone, and stratospheric water vapor. Two methods were used to quantify the relative climate impacts of the pathway for hydrogen as compared to that of the fossil fuels being replaced. The first is technology warming potential (TWP)[107] which compares the cumulative radiative forcing from continuous emissions for the two pathways considering 10, 20, 50, and 100 year timeframes. The second method is a comparison of the total emissions in CO2e using GWP for the 20 and 100 year time scales. The results indicate that green hydrogen pathways consistently reduce warming impacts from fossil fuel technologies by more than 60% for all time scales regardless of emission rate; and when emission rates are around 1%, the climate benefits jump to greater than 90%. The article also mentions that displacement of fossil fuels with hydrogen may reduce other co-emitted pollutants such as carbon monoxide (CO) and N_2O and volatile organic compounds (VOC) that are indirect GHGs that impact atmospheric chemistry. Finally, the article advocates for broader temporal analysis in climate impact assessments to capture both long-term and near-term effects and emphasizes the need for comprehensive assessments in hydrogen technology deployment to accurately evaluate its role in decarbonization strategies.

A detailed comparison of potential GHG emissions reductions of Angeles Link as compared to alternatives is beyond the scope of the Phase 1 feasibility analyses. The degree of analysis that could be reasonably completed at this feasibility stage to compare Angeles Link to other decarbonization pathways is included in the separate Alternatives Study, Cost Effectiveness Study, and Environmental Analysis.

The EDF blog post[108] "New research reaffirms hydrogen's impact on the climate, provides consensus," discusses that maintaining leakage of hydrogen at a minimum will depend on technological advancements related to direct measurement technologies that detect even small leaks. Minimal leakage will support the full advantages of the benefits of switching from fossil fuels to hydrogen.

[108] Ocko. I and S. Hamburg, EDF Blog, July 19, 2023, New research reaffirms hydrogen's impact on the climate, provides consensus, https://blogs.edf.org/energyexchange/2023/07/19/new-research-reaffirms-hydrogens-impact-on-the-climate-provides-consensus/

The article "Climate Impacts of Hydrogen and Methane Emissions Can Considerably Reduce the Climate Benefits across Key Hydrogen Use Cases and Time Scales"[109] also highlights hydrogen's potential for leakage. Additionally, the article "Wide Range in Estimates of Hydrogen Emissions from Infrastructure,"[110] published in Frontiers and recommended by stakeholders, notes that emission rates can vary widely across different components of the value chain, such as transmission and distribution pipelines and storage systems, reflecting variability.

The recent National Petroleum Council (NPC) Report[111] mentions that initial research shows that hydrogen leakage across the global value chain could reduce the climate benefits of hydrogen with greater climatic impact in the near term. Specifically, the report indicates that recent studies suggest that every 1% of value chain hydrogen leakage would reduce the climate benefit by 1.2% to 4.2% in the near term (20 years) and 0.4% to 1.3% in the long-term (100 years). The Report also suggests that to completely understand the climate impacts of hydrogen leakage, highly sensitive hydrogen direct measurement tools that are not yet widely available are needed to quantify leakage at real world facilities.

The article "Global modeling of hydrogen using GFDL-AM4.1: Sensitivity of soil removal and radiative forcing," mentions that hydrogen is the second most abundant reactive trace gas in the atmosphere with a global mean concentration of approximately 530 ppbv. Source of hydrogen are approximately 30% from fossil fuel combustion and 55% from formaldehyde photolysis. Over 80% of hydrogen removal from the atmosphere is attributed to soil uptake.[112]

Collectively, these studies underscore the importance of a comprehensive temporal analysis of GHG emissions from hydrogen sources. They advocate for the integration of these findings into policy and commercial decisions to minimize hydrogen's climate footprint. This includes designing infrastructure to minimize the potential for leakage and GHG emissions, enhancing the accuracy of direct hydrogen measurements, and expanding estimation methodologies to include short-term and long-term impacts. The ongoing research efforts are crucial for refining our understanding of hydrogen's role in climate dynamics and developing robust strategies to manage its emissions in the context of global climate goals. Given the variability observed across these models, scholarly research stresses the critical need for stringent controls on hydrogen leakage during its production, storage, and transport processes to mitigate its unintended climatic effects. These implications are being carefully considered and opportunities to minimize the potential for leakage is discussed in the parallel Phase One Leakage Study.

9.2 HYDROGEN LEAKAGE IMPACT ON PROJECTED OVERALL GHG EMISSIONS REDUCTIONS

In response to stakeholder input, the parallel Final Leakage Study Report provides a high-level estimate of potential leakage scenarios for general hydrogen infrastructure and for anticipated Angeles Link infrastructure. This estimation remains preliminary as detailed design and engineering data is not yet available for either the general or Angeles Link infrastructure.

9.2.1 General Infrastructure

For general infrastructure, the Final Leakage Study Report compiles leakage data across various stages of hydrogen infrastructure—including production, compression, aboveground storage, underground storage, and transmission—utilizing 25 distinct data points. From this compilation, a median leakage rate of 0.24% and an average rate of 0.92% were identified. These rates were then applied to estimate potential leakage across low, medium, and high throughput scenarios for Angeles Link. This modeling provides an initial quantitative framework for understanding potential losses due to leakage, albeit with uncertainty pending further infrastructure specification and development.

The Final Leakage Study Report provides high-level estimates of potential hydrogen leakage. These estimates range from 1,200 MT/yr for the conservative demand scenario using the median leakage estimate to 13,800 MT/yr for the ambitious demand scenario using the average leakage estimate.

To estimate the potential impact to climate change, a conservative method is used involving the range of estimated volumetric leakage rates, as well as the range of effective GWP 100 estimated for hydrogen from existing scientific studies. For the purposes of this analysis, the estimated amounts are assumed to be equivalent to GHG emissions. This assumption allows for evaluating the potential environmental impact relative to the GHG emission reduction estimates discussed in this Final GHG Study Report.

The Global Warming Potentials for hydrogen are used to convert the amount of leaked hydrogen into CO_2e. The GWP values specifically for a 100-year horizon range from 1.9 to 18, according to different studies summarized in Table 17. Using these GWP values, the potential GHG impact from leakage is calculated as follows:

- Lower Estimate: 1,200 MT/yr of hydrogen x 1.9 (minimum GWP100) = 2,280 MT CO_2e/yr
- Upper Estimate: 13,800 MT/yr of hydrogen x 18 (maximum GWP100) = 248,400 MT CO_2e/yr

These GHG values, ranging from 2,280 MT CO_2e/yr to 248,400 MT CO_2e/yr, are then compared to the projected overall GHG reductions from the project (end-user reductions minus infrastructure emissions), which are estimated at 9.0 MMTPY (as shown in Table ES-1). This comparison shows that the impact of hydrogen leakage on the overall GHG reductions ranges from about 0.03% to 2.8%. In other words, this high-level methodology indicates that the impact from combustion associated with new hydrogen infrastructure to the predicted overall GHG emissions reductions would be very low (i.e., less than 3% for high throughput scenario).

9.2.2 Angeles Link Infrastructure

For Angeles Link infrastructure, the Final Leakage Study Report compiles leakage data for compression and transmission using 10 distinct data points. From this compilation, a median leakage rate of 0.17% and an average rate of 0.27% were identified. These rates were then applied to estimate potential leakage across low, medium, and high throughput scenarios for Angeles Link. This modeling provides an initial quantitative framework for understanding potential losses due to leakage, albeit with uncertainty pending further infrastructure specification and development.

The Final Leakage Study Report provides high-level estimates of potential hydrogen leakage. These estimates range from 850 MT/yr for the low throughput scenario using the median leakage estimate to 4,065 MT/yr for the high throughput scenario using the average leakage estimate.

To estimate the potential impact to climate change, a conservative method is used involving the range of estimated volumetric leakage rates, as well as the range of effective GWP 100 estimated for hydrogen from existing scientific studies. For the purpose of this analysis, the estimated amounts are assumed to be equivalent to GHG emissions. This assumption allows for evaluating the potential environmental impact relative to the GHG emission reduction estimates discussed in this Final GHG Study Report.

The Global Warming Potentials for hydrogen are used to convert the amount of leaked hydrogen into CO_2e. The GWP values specifically for a 100-year horizon range from 1.9 to 18, according to different studies summarized in Table 17. Using these GWP values, the potential GHG impact from leakage is calculated as follows:

- Lower Estimate: 850 MT/yr of hydrogen x 1.9 (minimum GWP100) = 1,615 MT CO_2e/yr
- Upper Estimate: 4,065 MT/yr of hydrogen x 18 (maximum GWP100) = 73,170 MT CO_2e/yr

These GHG values, ranging from 1,615 MT CO_2e/yr to 73,170 MT CO_2e/yr, are then compared to the projected overall GHG reductions from the project (end-user reductions minus infrastructure emissions), which are estimated at 9.0 MMTPY (as shown in Table ES-1). This comparison shows that the impact of hydrogen leakage on the overall GHG reductions ranges from about 0.02% to 0.8%. In other words, this high-level methodology indicates that the impact to the predicted overall GHG emissions reductions would be very low (i.e., less than 1% for high throughput scenario) when considering the addition of potential GHG emissions from the two leakage sectors evaluated in the parallel Final Leakage Study Report. Scientific studies indicate that maintaining value chain leakage rates below 1% will increase climate benefits of clean renewable hydrogen to greater than 90%.[113]

As the project progresses, further refinements in infrastructure design, better information from end users, and technological advancements will likely provide more accurate data. This can help in more precisely quantifying the leakage and its impact on overall GHG emissions reductions. Additionally, further studies and data will allow a better understanding of the atmospheric effects of hydrogen, particularly through advanced modeling techniques.

[113] Sun, Tianyi, et al., 2024, Ibid.

10 CONCLUSIONS

The direct GHG combustion emission estimates were developed from data from both the Demand Study Demand Scenarios and Angeles Link Throughput Scenarios and are set forth in this Study. The GHG combustion emission estimates associated with Angeles Link set forth in this study are informative for Phase 1. This study acknowledges that based on available scientific research preliminarily reviewed, there is uncertainty about the potential tropospheric and atmospheric effects associated with leakage of hydrogen. Preliminary high-level estimates indicate that the potential for hydrogen leakage from infrastructure as compared to the overall GHG reductions may range from 0.03% to 2.8%. In other words, this high-level methodology indicates that the impact to the predicted overall GHG emissions reductions (end users minus infrastructure emissions) would be very low (i.e., less than 3% for high throughput scenario). The design details of the hydrogen infrastructure and the Angeles Link infrastructure as the project is further refined, and more details regarding third-party production, third-party storage, and end users, may further inform future quantification estimates of GHG emissions.

10.1 UNCERTAINTY

Global warming potentials from IPCC's AR6 report were utilized to calculate CO2e emissions within this study. While these AR6 values are the most recently published global warming potentials from the IPCC, it is likely that these values will continue to evolve as new science is published. There is uncertainty in how these global warming potential values will change in the future.

10.1.1 Infrastructure

Design of the new hydrogen infrastructure and Angeles Link infrastructure will be refined in future project stages, and as a result assumptions related to transmission of hydrogen, in addition to assumptions regarding third-party production and third-party storage, formed the basis of the GHG emissions estimates. Details regarding the hydrogen production process, and proportions of hydrogen intended to be produced from different methods, if more than one method is used, would reduce the uncertainty with respect to the estimated hydrogen production emissions estimates.

The evaluation of GHG emissions associated with water conveyance or transportation of materials such as biomass to production sites or biomass feed preparation are not included in this Study as these details are beyond the scope of the Phase 1 feasibility studies. For example, this Study assumed that biomass would be procured ready for combustion and removal of moisture would not be required on-site.

Estimates were developed based on hypothetical electrolysis, biomass gasification, and biogas in steam methane reforming scenarios where the combustion equipment is fueled by hydrogen. Details regarding quantity of hydrogen storage, location, and types (aboveground versus underground) of storage will inform refinement of these initial estimates. Additionally, distances and locations (primarily underground, and aboveground where necessary) of transmission pipelines will also provide details to refine the emission estimates. More accurate GHG emissions estimates related to infrastructure can be developed as designs evolve and details emerge.

10.1.2 End Users

As discussed previously in this report, there is a lack of data and clarity around a N_2O emissions factor for hydrogen combustion and therefore uncertainty regarding associated GHG emissions. There are many variables that may affect N_2O formation including different operating modes, lean combustion, control options, and lower combustion temperatures possible with hydrogen. Using a conservative value in these calculations may result in higher N_2O estimates than actual N_2O emissions. The conservative value of 2 ppm was selected for the calculations within this study developed based on information in the literature and incorporation of a margin of safety of 2, by doubling of the value.

There is uncertainty within the correction factor calculation approach for converting a mass basis emissions limitation for natural gas combustion to a mass basis emissions limitation for hydrogen combustion. One source of uncertainty arises from the lack of information around how the fuel type (including blended fuels) impacts the oxygen levels in the exhaust gas, and how that impacts the required oxygen correction factors in the conversion from volumetric to mass emissions for hydrogen combustion exhaust.

There is uncertainty in the correction factor calculation approach for converting natural gas emissions to a representative value for hydrogen. A source of uncertainty in this approach is the lack of information about how oxygen levels in the exhaust gas may vary between natural gas, hydrogen, and blends. In this study, it was assumed that a particular type of equipment combusting natural gas, hydrogen, or a blend would have the same exhaust oxygen concentration for all fuels. In-practice combustion characteristics for hydrogen turbines may result in higher or lower exhaust oxygen concentrations than what is observed in natural gas equipment. If exhaust oxygen concentration is higher for hydrogen than natural gas, emissions from hydrogen will increase compared to what is forecasted in this study.

Fossil fuel displacement volumes for diesel and gasoline from the Demand Study were utilized in the calculations within this study directly as provided for the mobility sector. Natural gas displaced by hydrogen and hydrogen demand projections were provided by the Demand Study and utilized in the calculations within this study as provided for the power generation and hard to electrify industrial sectors.

On-road vehicle GHG emissions factors were developed from the current EMFAC model, and off-road vehicle CO_2 emissions factors were developed from the current EMFAC model, while emissions factors from EPA were utilized for off-road vehicle CH_4 and N_2O emissions. The EMFAC model may be updated in the future, and EPA routinely updates their recommended emissions factors for GHG inventories document. It is uncertain how these emissions factors might change in the future.

10.2 KEY FINDINGS

Key findings for GHG emission reductions based on the Demand Study Scenarios are as follows.

- Projected up to nearly 17 and 36 million metric tons of CO2e per year removed from SoCalGas geographic service territory by end users by 2045 in conservative and ambitious demand scenarios of the Demand Study, respectively. The reductions are equivalent to the annual GHG emissions of approximately 45 and 96 natural gas fueled power plants, respectively per EPA Calculator.
- Mobility sector comprises 72.5% and 50.3% of overall GHG reductions based on the conservative and ambitious demand scenarios, respectively, in the year of 2045. The GHG reductions estimated for the conservative and ambitious demand scenarios in 2045 are equivalent to removing approximately 2.7 million and 4.3 million gasoline passenger vehicles off the roads per year, respectively.[114]
- Power generation and hard to electrify industrial sectors comprise 41.7% and 8.1% of the overall GHG reductions, respectively, based on the ambitious demand scenario.
- Power generation and hard to electrify industrial sectors comprise 23.6% and 3.9% of overall GHG reductions, respectively, based on the conservative demand scenario in 2045.
- Infrastructure GHG emissions are projected to be negligible when compared to overall emission reductions, at 0.17% and 0.25% of end-user reductions for conservative and ambitious demand scenarios, respectively.

Key Findings: Angeles Link Throughput Scenarios

The key findings for GHG emission reductions for Angeles Link Throughput Scenarios, which accounts for emissions from not just transmission of hydrogen, but also from third-party production and storage as well as end users, are as follows and are discussed further herein.

[114] EPA, 2023a, GHG Calculator, Ibid.

- Projected about 4.5 and 9 MMT of CO_2e per year removed from SoCalGas's geographic territory by end users by 2045 in Angeles Link Low and High Throughput Scenarios, respectively.
- Mobility sector comprises 72.5% and 50.3% of overall GHG reductions based on the Angeles Link Low and High Throughput value scenarios, respectively, in 2045. The GHG reductions estimated for the Low and High Throughput Scenarios in 2045 are equivalent to 725,000 and more than 1 million gasoline passenger vehicles driven for one year, respectively.[115]
- Power generation and hard to electrify industrial sectors comprise 41.7% and 8.1% of overall GHG emission reductions, respectively, based on the High Throughput Scenario.
- Power generation and hard to electrify industrial sectors comprise 23.6% and 3.9% of overall GHG emission reductions, respectively, based on the Low Throughput Scenario in 2045.
- Infrastructure GHG emissions are projected to be negligible when compared to overall emission reductions at 0.17% and 0.25% of end-user reductions for Low and High Throughput Scenarios, respectively.

Additional details related to both the Demand Scenarios and Angeles Link Throughput Scenarios are provided below.

2030 Ambitious Demand Scenario: In 2030, the Ambitious Demand Scenario predicts a reduction of about 6 MMTPY of CO_2e due to hydrogen replacing fossil fuels. This reduction includes the emissions from producing, storing, and transmitting hydrogen. This amount of reduction is comparable to the energy use of about 740,000 homes for one year, according to the EPA's greenhouse gas (GHG) calculator.[116] In terms of specific contributions, Angeles Link is expected to meet about 25% of the projected hydrogen demand identified in the Demand Study. This means that the specific GHG reductions attributed to Angeles Link under the High Throughput Scenario are estimated at about 1.45 million MT CO_2e per year, which is equivalent to the energy use of approximately 189,000 homes for one year.

2045 Ambitious Demand Scenario: By 2045, the scenario estimates an overall reduction in CO_2e emissions of about 36 MMTPY, again due to the displacement of fossil fuels by hydrogen. These reductions are equivalent to the annual electricity usage of over 4.6 million homes, as per the EPA's calculator. Angeles Link is expected to supply the same percentage (about 25%) of the total hydrogen demand in SoCalGas service territory, as projected in the Ambitious Demand Scenario. As a result, the GHG emissions

[115] EPA, 2023a, GHG Calculator, Ibid.
[116] EPA, 2023a, GHG Calculator, Ibid.

reductions specifically associated with Angeles Link in the High Throughput Scenario for 2045 are estimated at about 9.0 million MT CO2e per year. This would correspond to the energy use of roughly 1.1 million homes for one year.

Mobility Sector: In the Mobility sector, the estimated CO2e reductions under the ambitious demand scenario are approximately 4.4 million MT in 2030 and about 18 million MT by 2045. The reductions by 2045 are equivalent to the emissions from around 4.3 million gasoline-powered passenger vehicles driven for a year. The sector accounts for between 50% to 83% of total GHG emissions reductions, varying by scenario and year. The largest contributors are heavy-duty vehicles (55.5% in 2030 and 62.8% in 2045), followed by buses (33.6% in 2030 and 22.0% in 2045), and medium-duty vehicles (7.3% in 2030 and 9.7% in 2045). Reductions from on-road vehicles outweigh those from off-road vehicles, mainly due to the higher displacement of fossil fuels. In the High Throughput Scenario, the reductions for 2030 are about 1.1 million MT CO2e per year, increasing to about 4.6 million MT CO2e by 2045. The 2045 reductions would be equivalent to the emissions from 1 million gasoline-powered vehicles driven for a year.

Power Generation Sector: In the Power Generation sector, it's projected that by 2030, there could be a reduction of 0.16 million MT of CO2e under the ambitious demand scenario, and by 2045, this could increase to about 15 million MT CO2e. Over 78% of these reductions are expected from the peaker and baseload plant sub-sectors in all years under this scenario with the remaining reductions attributable to the cogeneration sub-sector. By 2045, these reductions are equivalent to the yearly electricity consumption of approximately 1.9 million homes, according to the EPA's calculator. Under the High Throughput Scenario, the reductions are estimated at about 41,000 MT CO2e per year for 2030 and about 3.8 million MT CO2e per year by 2045. The reductions for 2045 under this scenario are comparable to the energy use of around 480,000 homes for one year.

Hard to Electrify Industrial Sectors: In the industrial sectors that are difficult to electrify, the estimated CO2e reductions under the ambitious demand scenario are around 1.1 million MT in 2030 and could rise to about 2.9 million MT by 2045. The 2045 reductions would be equal to the annual electricity usage of about 365,000 homes. In this scenario, refineries are the largest contributors, accounting for 65.5% of reductions in 2030, followed by the Food and Beverage sector (13.4%), Stone, Glass, and Cement (12.1%), and Metals (5.3%). Please note that refineries are only considered in the Ambitious Demand Scenario and refineries comprise about one-quarter of the Demand in this scenario. These percentages remain consistent from 2030 to 2045. In the High Throughput Scenario, the reductions are estimated at about 290,000 MT CO2e per year for 2030 and about 730,000 MT CO2e per year by 2045. The 2045 reductions equate to the energy use of around 96,000 homes for one year.

Hydrogen Infrastructure Emissions: Emissions associated with new hydrogen infrastructure are evaluated. The results of the conservative estimate prepared represent a small fraction of the emissions reductions achieved by end-users adopting hydrogen in the study region.

Specifically, in the Ambitious Demand Scenario:

- By 2030, emissions from the new hydrogen infrastructure are estimated at about 16,600 MT of CO2e per year. This accounts for 0.29% of total CO2e reductions expected from end-users based on hydrogen usage projections.
- By 2045, these emissions increase to about 87,900 MT per year of CO2e, which constitutes 0.25% of the total CO2e reductions from end-users. This accounts for 0.25% of total CO2e reductions expected from end-users based on hydrogen usage projections.

For Angeles Link, under the High Throughput Scenario:

- In 2030, the estimated emissions attributed to the new infrastructure are estimated to be around 4,200 MT of CO2e per year. This accounts for 0.29% of total CO2e reductions expected from end-users based on hydrogen usage projections.
- By 2045, this figure is projected to rise to 22,300 MT of CO2e per year. This accounts for 0.25% of total CO2e reductions expected from end-users based on hydrogen usage projections.

11 STAKEHOLDER FEEDBACK

SoCalGas presented opportunities for the PAG and CBOSG to provide feedback at four key milestones during the course of conducting this study: (1) the draft description of the Scope of Work, (2) the draft Technical Approach, (3) Preliminary Data and Findings, and (4) the Draft Reports. These milestones were selected because they are critical points at which relevant feedback can meaningfully influence the study.

Table 18
Key Milestone Dates

Milestone	Date Provided to PAG/CBOSG	Comment Due Date	Responses to Comments in Quarterly Report[1]
1. Scope of Work	7/6/2023	7/31/2023	Q3 2023
2. Technical Approach	9/7/2023	10/20/2023	Q4 2023
3. Preliminary Data and Findings	2/27/2024	3/29/2024	Q1 2024
4. Draft Report	7/10/2024	8/7/2024	Q3 2024

Feedback provided at the PAG/CBOSG meetings is memorialized in the transcripts of the meeting. Written feedback received is included in the quarterly reports, along with responses. Meeting transcripts are also included in the quarterly reports. The quarterly reports are submitted to the CPUC and are published on SoCalGas's website.

Feedback was incorporated as applicable at each milestone throughout the progression of the study. Some feedback was not incorporated for various reasons, including feedback that was already within the study scope, feedback that was outside the scope of the Phase 1 Decision or feasibility study, and feedback that raises issues better suited for third parties to address.

In response to feedback received following SoCalGas's presentation of the Preliminary Findings and Data to the PAG/CBOSG, this Study includes an estimate of the impact to estimated GHG reductions of a preliminary high-level volumetric estimate of the potential for leakage from hydrogen infrastructure from the Leakage Study Report, as well as presenting a summary of the estimated Global Warming Potential (GWP) 100 and GWP 20 for hydrogen available in the literature.

A summary of stakeholder input that was incorporated throughout the development of the GHG Study and into this Final Report is provided in Table 19: Summary of Incorporated Stakeholder Feedback. All feedback received, whether incorporated into the study or not as described above, has been recorded in the quarterly reports, along with SoCalGas's responses. Additionally, some administrative and other minor corrections were made to the Final GHG Study Report for clarity.

Table 19
Summary of Incorporated Stakeholder Feedback

Thematic Comments from PAG/CBOSG Members	Incorporation of and Response to Feedback
Overall GHG Reductions Stakeholder indicated that hydrogen leakage should be considered in the GHG emissions impact calculations. They requested that volumetric leakage estimates and associated impacts to climate change be discussed and a volumetric analysis be included in the Leakage Study and GHG Study.	In response to stakeholder comments, the range of preliminary high-level volumetric estimates quantifying the potential for leakage, provided in the Leakage Study was used in the GHG Study to predict a high-level range of potential impacts to the estimated overall GHG reductions associated with general new hydrogen infrastructure and with Angeles Link infrastructure using the potential for leakage values found during a literature review. The results are provided in Section 9.3.
Global Warming Potential Stakeholders requested an evaluation of the climate risks of projected GHG emissions and inquired about the type of evaluation that will be conducted to determine the indirect warming potential of hydrogen leakage. Stakeholders expressed interest in having the GHG Study prepared using both GWP 100 and GWP 20 values for hydrogen and examining climate impacts of different hydrogen leakage rates.	Although the IPCC has not assigned a GWP for hydrogen, scientific literature indicates that hydrogen behaves as an indirect GHG. In response to stakeholder comment, a summary of the estimated GWP 20 and GWP 100 values for hydrogen based on a literature review is now provided in Table 17.
Carbon Intensity Stakeholders suggested that the GHG Study should include carbon intensity and	Consistent with stakeholder comments, the GHG Study evaluates direct GHG emissions associated with hydrogen

Table 19 Summary of Incorporated Stakeholder Feedback	
Thematic Comments from PAG/CBOSG Members	**Incorporation of and Response to Feedback**
lifecycle emissions. There was a request to estimate GHG related to third-party production, specifically from water procurement, conveyance, and treatment; and from feed preparation and transport of biomass. Stakeholders also requested the inclusion of the carbon intensity of delivered hydrogen based on production and transport scenarios.	combustion related to new infrastructure, specifically third-party production, third-party storage, and transmission of hydrogen, as well as GHG emissions reductions associated with displaced fossil fuels by end users in the mobility, power generation, and hard-to-electrify industrial sectors. While lifecycle assessments require a level of detail beyond the scope of this feasibility study and have not been included, a summary of carbon intensity information from the literature is provided in Appendix B.
Third-Party Production Stakeholders requested clarification regarding assumptions and resulting GHG emissions associated with the three analyzed third-party production options – electrolysis, biomass gasification, and steam methane reforming.	In response to stakeholder feedback, the Study clarifies that an assumption was made that biomass would be procured ready for combustion and moisture removal would not be required on-site. The Study evaluated GHG associated with SMR using RNG as a feedstock and clean renewable hydrogen as a fuel for the heating equipment. Extensive details regarding GHG emissions associated with third-party production options have also been provided in Appendices A and B in response to this request.
Demand Study Assumptions Stakeholders commented that the Demand Study assumptions focused too heavily on regulatory and policy decisions.	An explanation of the GHG Study's reliance on information from the Demand Study was added to this report in response to stakeholder comment. The GHG Study includes analysis based on the three scenarios from the Demand Study and the three scenarios of currently projected throughput for Angeles Link. The GHG Study explains that SoCalGas's Demand Study projections were based on

Table 19 Summary of Incorporated Stakeholder Feedback	
Thematic Comments from PAG/CBOSG Members	**Incorporation of and Response to Feedback**
	independently developed assumptions and analysis of potential hydrogen uptake in the SoCalGas service territory. The Demand Study was peer reviewed by experts at third parties, including NREL, South Coast Air Quality Management District (SCAQMD), University of California Los Angeles (UCLA), UCI, and UC Davis (UCD).
Hydrogen Blending Stakeholders had questions regarding the blending of natural gas with hydrogen in the Angeles Link pipelines.	In response to stakeholder comment, the document clarifies that since the CPUC has mandated that Angeles Link only deliver 100% clean renewable hydrogen, blending of hydrogen with natural gas, if any, would be done behind the meter at the end users' facilities, as discussed in Section 3.5.2.3.
Decarbonization Pathways Stakeholders indicated that anticipated GHG emission reductions for the pipeline scenario should be evaluated with respect to optimization and relative efficiencies of other decarbonization pathways.	In response to stakeholder comment, Section 9.1 clarifies that a detailed comparison of potential GHG emissions reductions of Angeles Link compared to alternatives is beyond the scope of the Phase 1 feasibility analyses. The degree of analysis that could be reasonably completed at this feasibility stage to compare Angeles Link to other decarbonization pathways is included in the separate Alternatives Study, Cost Effectiveness Study, and Environmental Analysis.
End Users Stakeholders expressed concerns that indicated that Angeles Link will not serve refueling stations and that there isn't	Consistent with stakeholder comments and as described in the Routing Analysis, SoCalGas's route selection process evaluates directional pathways that account for engineering, environmental,

Table 19 Summary of Incorporated Stakeholder Feedback	
Thematic Comments from PAG/CBOSG Members	**Incorporation of and Response to Feedback**
sufficient information regarding routing with respect to end user locations.	social, and environmental justice features along the four potential preferred routes. A final preferred route will be selected in Phase 2 of Angeles Link. This clarifying information is included in Section 5.2.
Leakage at End Users Stakeholders requested an analysis of the potential for leakage associated with end users of hydrogen.	In response to stakeholder comments, additional information would be needed to expand the scope of the Leakage Study to project hydrogen leakage rates for each sub-sector within the three primary sectors of potential end-users (mobility, power generation, and hard-to-electrify industrial). This Phase 1 analysis was conducted using a top-down approach, at a high level rather than at a granular facility level and equipment specific level. The limited information found regarding potential leakage at end users was included in Global Response 2 in the Quarter 2 report and in Section 4.1.1 of the Leakage Study. Further investigation would be needed to evaluate whether any of the estimated values among the wide ranges would be appropriate predictors for Angeles Link end users.
Methane Leakage Stakeholders commented that upstream methane emissions should be considered.	In response to stakeholder comments, evaluation of methane leakage in the hydrogen industry is outside the scope of this feasibility analysis, as discussed in the Executive Summary and Section 3.2.
Project Construction Stakeholders suggested that GHG emissions from the construction of Angeles Link should be evaluated.	In response to stakeholder comments, Section 2 was updated to address the scope of the GHG Study and explains that project specific construction emissions will be evaluated as a part of

Table 19 Summary of Incorporated Stakeholder Feedback	
Thematic Comments from PAG/CBOSG Members	**Incorporation of and Response to Feedback**
	the CEQA/NEPA process which will be based on a defined project description that includes the pipeline route (the selection of which will occur as a part of a subsequent phase of Angeles Link), ancillary equipment, earthwork and construction equipment.
Literature Review Several stakeholders provided reports and literature to review and incorporate into the GHG Study.	In response to stakeholder feedback, the Study includes a review of relevant literature provided by stakeholders the reference list has been updated accordingly.

Summary of Literature Provided by Stakeholders

Specific literature provided has been evaluated and relevant information has been incorporated, as appropriate, including, but not limited to:

12 GLOSSARY

Anthropogenic causes - Anthropogenic causes are causes of environmental problems that are a result of human activities. Examples of anthropogenic causes are energy-related activities, such as combustion of fossil fuels in the electric utility and transportation sectors, and the anthropogenic greenhouse effect, which is due to greenhouse gases emitted by humans, leading to global warming.

Autoignition temperature – The minimum temperature that a substance mixed with air will ignite and burn without an ignition source.

Blended fuels – Blended fuels are mixtures of traditional and alternative fuels in varying percentages. Blends can be thought of as transitional fuels. The lowest-percentage blends are being marketed and introduced to work with current technologies while paving the way for future integration, in this case, eventual usage of 100% hydrogen fuel.

Carbon-based fuel (also includes fossil fuel) – Hydrocarbon materials of biological origin. Carbon-based fossil fuel includes decomposing plants and other organisms, buried beneath layers of sediment and rock. These fuels have taken millennia to become the carbon-rich deposits we now call fossil fuels. These fuels include coal, oil, and natural gas.

Clean renewable hydrogen – Clean renewable hydrogen is defined as hydrogen that does not exceed 4 kilograms of CO_2e produced on a lifecycle basis per kilogram of hydrogen produced and does not use fossil fuel in the hydrogen production process where fossil fuel is defined as a mixture of hydrocarbons including coal, petroleum, or natural gas, occurring in or extracted from underground deposits per Decision 22-12-055 dated December 15, 2022.

Cogeneration – Cogeneration is the use of a heat engine or power station to generate electricity and useful heat at the same time. Cogeneration is a more efficient use of fuel or heat, because otherwise-wasted heat from electricity generation is put to some productive use. These plants recover otherwise wasted thermal energy for heating.

Compressors – A compressor is a mechanical device that increases the pressure of a gas by reducing its volume. Compressors are similar to pumps: both increase the pressure on a fluid and both can transport the fluid through a pipe. The main distinction is that the focus of a compressor is to change the density or volume of the fluid, which is mostly only achievable on gases. Gases are compressible, while liquids are relatively incompressible, so compressors are rarely used for liquids. The main action of a pump is to pressurize and transport liquids.

Combustion units – A combustion unit generates mechanical power by combustion of a fuel. Combustion units are of two general types: internal combustion engines and external combustion units.

Decarbonize – Decarbonization can mean moving away from energy systems that produce carbon dioxide (CO_2) and other greenhouse gas emissions. Energy decarbonization involves shifting the entire energy system in an attempt to stop carbon emissions from entering the atmosphere before they are ever released — this involves decarbonizing power grids, decarbonizing supply chains, and utilizing carbon sequestration in the pursuit of net-zero emissions and a carbon-neutral global economy.

Density – the mass per unit volume of a substance.

Diffusivity – Diffusivity is a measure of the capability of a substance or energy to be diffused or to allow something to pass by diffusion. Diffusivity refers to the spreading of something or making it less concentrated.

Electrolyzer – An electrolyzer uses electrolysis as a method for carbon-free hydrogen production (green hydrogen) from renewable and nuclear resources. Electrolysis is the process of using electricity to split water into hydrogen and oxygen. This reaction takes place in an electrolyzer that can range in size from small, appliance-sized equipment that is well-suited for small-scale distributed hydrogen production to large-scale, central production facilities that could be tied directly to renewable or other non-greenhouse-gas-emitting forms of electricity production.

End-users – An end-user uses the hydrogen delivered by Angeles Link.

Engine – a machine that converts thermal energy into useful work (e.g., electricity of shaft power) to produce force and motion.

Exhaust gas aftertreatment – a device that reduces exhaust emissions from combustion equipment such as turbines and engines. It cleans exhaust gases to ensure the engines meet emission regulations. The main function of an aftertreatment system is to reduce emissions post combustion.

External combustion – The process of combining heat, fuel, and oxygen without the use of a combustion chamber to produce thermal energy.

Feasibility study – A feasibility study is an assessment of the practicality of a proposed project plan or method. For example, asking “Is this feasible?” by analyzing implementation and operational factors.

Feedstock – Feedstock is the material that is used in some hydrogen production equipment such as renewable natural gas and biomass.

Flammability range – The range of air-to-fuel ratios for which a substance will burn when exposed to an ignition source. The low end of this range is “rich” combustion where excess fuel inhibits combustion. The high end of this range is “lean” combustion where excess air inhibits combustion.

Global Warming Potential (GWP) – Global warming potential (GWP) is a measure of how much infrared thermal radiation a greenhouse gas added to the atmosphere would absorb over a given time frame, as a multiple of the radiation that would be absorbed by the same mass of added carbon dioxide (CO_2). GWP is 1 for CO_2. For other gases it depends on how strongly the gas absorbs infrared thermal radiation, how quickly the gas leaves the atmosphere, and the time frame being considered.

Green hydrogen – Green hydrogen is produced through water electrolysis process by employing renewable electricity. The reason it is called green is that there is no CO_2 emission during the production process. Water electrolysis is a process which uses electricity to decompose water into hydrogen gas and oxygen.

Heavy-duty transportation – Heavy-duty transportation includes flatbed trailers, wide load hauling, large trucks, and freight trucks.

Hydrogen – Hydrogen is a colorless, odorless, tasteless, flammable gaseous substance that is the simplest member of the family of chemical elements.

Hydrogen fuel cell - A hydrogen fuel cell is an electrochemical cell that produces a current that can work using a spontaneous redox reaction. The combination of the two half-cell potentials for the electrochemical reaction creates a positive potential for cells. In general, fuel cells are different from most batteries in that they require a continuous source of fuel and oxygen (usually from air) to sustain the chemical reaction, whereas in a battery the chemical energy usually comes from substances that are already present in the battery. Fuel cells can produce electricity continuously for as long as fuel and oxygen are supplied. The only byproduct of a hydrogen fuel cell is water vapor.

Ignition energy – The minimum energy required to initiate the self-sustained combustion of a substance.

Infrastructure – Infrastructure are the resources such as pipelines and compressors required for an activity such as transmission of hydrogen.

Internal combustion – The process of combining heat, fuel, and oxygen within a combustion chamber where the combustion gasses themselves are the working fluid.

Methane – Methane is a chemical compound with the chemical formula CH_4 (one carbon atom bonded to four hydrogen atoms). It is the main component of natural gas.

Methodology – Methodology is the general research strategy that outlines the way in which research is to be undertaken and, among other things, identifies the methods to be used in it. These methods, described in the methodology, define the means or modes of data collection or, sometimes, how a specific result is to be calculated.

N_2O – N_2O is nitrous oxide, a greenhouse gas commonly known as laughing gas or nitrous, and is a chemical compound, an oxide of nitrogen. At room temperature, it is a colorless non-flammable gas, and has a slightly sweet scent and taste.

NOx – NOx is shorthand for nitrogen oxides (comprised of NO and NO_2) which is an air pollutant subject to air quality regulations formed during combustion of fossil fuels and a precursor to ozone.

Reciprocating compressors – A reciprocating compressor uses a linear drive to move a piston or a diaphragm back and forth to compress a gas. This motion compresses the gas by reducing the volume it occupies. Reciprocating compressors are the most used compressors for applications that require a very high compression ratio (compression ratio is the ratio of the pressure at the outlet of the compressor over the pressure at the inlet of the compressor).

Refining – Refining is removing impurities or unwanted elements from a substance, typically as part of an industrial process.

Stationary source – A stationary source refers to a qualitative term used to describe any fixed emitter of air pollutants, such as power plants, oil refineries, and heavy industrial facilities.

Steam generating units – Industrial/commercial/institutional steam generating units are boilers that are capable of combusting over 10 million international British thermal units per hour (MMBtu/hr) of fuel. A boiler or steam generator is a device used to create steam by applying heat energy to water.

Stoichiometric ratios/calculations – Stoichiometric ratios/calculations are used to analyze the relationship between the weights of reactants and products before, during, and following chemical reactions. Stoichiometry is founded on the law of conservation of mass where the total mass of the reactants equals the total mass of the products, leading to the insight that the relations among quantities of reactants and products typically form a ratio of positive integers. This means that if the amounts of the separate reactants are known, then the amount of the product can be calculated. Conversely, if one reactant has a known quantity and the quantity of the products can be empirically determined, then the amount of the other reactants can also be calculated.

Throughput – Throughput is the amount of a product or service that is provided.

Turbines - A turbine is a rotary mechanical device that extracts energy from a fluid flow and converts it into useful work. The work produced can be used for generating electrical power when combined with a generator. A turbine is a turbomachine with at least one moving part called a rotor assembly, which is a shaft or drum with blades attached. Moving fluid acts on the blades so that they move and impart rotational energy to the rotor. In a gas turbine, the turbine is driven by expansion of hot gases. In a steam turbine, expanding steam drives the turbine. The turbine can do mechanical work or be used to generate electricity.

Appendix A: Development and Application of GHG Emission Factor for Hydrogen Combustion

Combustion of hydrogen is anticipated to have zero or potentially trace GHG emissions. To account for the potential N_2O emissions that may form during combustion since N_2O is a GHG, in the absence of published N_2O emissions factors for hydrogen combustion, the following approach was used to develop hydrogen emissions factors based on studies. Details regarding assumptions made to apply the N_2O emission factor are also discussed below.

Development of GHG Emission Factor

Studies evaluating the formation of N_2O from the combustion of hydrogen typically fall into two categories: modeling or direct measurement. For the modeling studies, various models, variable inputs, and boundary conditions are used to account for the unique properties of hydrogen and minimization of air pollutant emissions. Direct measurement studies addressing N_2O formation from the combustion of hydrogen are typically performed on equipment that was not originally designed to account for the unique combustive properties of hydrogen.

A paper published in the International Journal of Hydrogen Energy in 2017 by a team at UCI investigated whether N_2O emission could be formed and emitted by the combustion of various fuels that did not contain nitrogen.[117] The study evaluated natural gas with up to 70% hydrogen added (by volume). The results indicated that direct N_2O emissions were observed in greater volumes during transient events such as ignition and blowoff. It also found that steady state combustion of hydrogen-enriched natural gas flames can lead to the direct emissions of N_2O when operated at very lean conditions, made possible by the stabilizing effects of hydrogen. The study measured N_2O concentrations at various fuel–air equivalence ratios, phi. The fuel–air equivalence ratio is defined as the ratio of the fuel-to-oxidizer ratio to the stoichiometric fuel-to-oxidizer ratio. If the fuel-air equivalence ratio is less than 1, the mixture is considered lean (air is in excess). The study compared the lean burnoff experimental measurements with GRI 3.0 and University of California San Diego (UCSD) chemical reaction mechanisms,[118] with the UCSD mechanism following the experimental trends. The USCD San Diego Mechanism is used for modeling combustion applications as a chemical-kinetic mechanism with 57 species

[117] Colorado, A., V. McDonell and S. Samuelsen, 2017, Ibid.
[118] University of California at San Diego, 2023, Chemical-Kinetic Mechanisms for Combustion Applications, University of California at San Diego Mechanical and Aerospace Engineering (Combustion Research), San Diego Mechanism web page, https://web.eng.ucsd.edu/mae/groups/combustion/mechanism.html

in 268 reactions.[119] GRI 3.0 is a mechanism for modeling natural gas combustion, including 325 reactions and 53 species.[120] As noted in this study, N_2O is rapidly consumed at high temperatures or when equivalence ratio is close to the stoichiometric point ($\phi = 1$). Therefore, combustion parameters such as a higher ratio of air-to-fuel (leaner combustion) and lower combustion temperatures that are utilized to minimize the formation of NOx emissions from the combustion of hydrogen fuels may potentially have the opposite effect on direct N_2O emissions. These effects need to be studied further since hydrogen combustion allows for leaner mixtures and stable operation at lower temperatures.

In a white paper prepared by the National Energy Technology Laboratory (NETL), hydrogen combustion emissions are evaluated. Similar to other literature, it is noted that thermal NOx is the prevalent form of NOx emissions for most high-temperature combustion (higher than 1,500°C). It is noted that in regions of the flame where there is a lack of oxygen, N_2O can also be formed from the under-oxidation of nitrogen. N_2O formation through this intermediate mechanism during combustion is generally very rare compared to other NOx compounds according to the paper "A Literature Review of Hydrogen and Natural Gas Turbines: Current State of the Art with Regard to Performance and NOx Control."[121]

A 1994 paper by Kramlich et al. indicates that in most nitrogen free gas fuel combustion systems the flame temperature is sufficiently high that any N_2O formed in the flame zone is destroyed before the gases are emitted.[122]

A modeling study completed by Duan et al. published in 2017 studied the mechanisms for NOx formation in a hydrogen internal combustion engine under high load found that

[121] National Energy Technology Laboratory, 2022, A Literature Review of Hydrogen and Natural Gas Turbines: Current State of the Art with Regard to Performance and NOx Control, White Paper DOE/NETL-2022/3812, August 12, https://www.netl.doe.gov/sites/default/files/publication/A-Literature-Review-of-Hydrogen-and-Natural-Gas-Turbines-081222.pdf

[122] Kramlich, J.C. and W.P. Linak, 1994, Nitrous oxide behavior in the atmosphere, and in combustion and industrial systems, Progress in Energy and Combustion Science 20(2): 149-202, https://www.sciencedirect.com/science/article/abs/pii/0360128594900094?via%3Dihub

the N_2O concentration increased during the period of combustion. However, N_2O concentration at the end of the modeled process was less than 1 ppm. [123]

Table A-1
Summary of Experimental Data of Hydrogen Combustion by Fuel Type

Fuel (Equipment)	Metric	Value	Units	Author
H_2:NG Blend (Burner)	Experimental	0.55	ppm (wet)	Colorado et al., 2017
H_2 (HICE)	Model Transient	6	ppmvd	Duan et al., 2017
H_2 (HICE)	Model Typical	1	ppmvd	Duan et al., 2017
H_2 (Residential Boiler)	Experimental	0.41	ppmvd	Galbraith, 2023[124]

As discussed above, data on N_2O emissions from 100% hydrogen combustion is sparse. In the table above, experimental data for blended hydrogen fuel, N_2O modeled data, and experimental data for hydrogen combustion are summarized. While data was available for ignition and transient combustion, the focus was on establishing a N_2O emission factor for steady-state combustion to best reflect anticipated combustion emissions. In collaboration with UCI, an evaluation of the available data was conducted. An average of the experimental data including the standard deviation was considered, but in effort to avoid the potential of underestimating N_2O emissions, the worst-case modeling data was chosen as the basis for estimated N_2O emissions from hydrogen combustion. It was further decided to add an additional layer of conservatism by applying a margin of safety of two. This approach utilizes the best data currently available and the inclusion of a margin of safety accounts for the uncertainty and the limited dataset. The conclusion is that a N_2O emission factor of 2 ppmvd was used for this study.

Application of GHG Emission Factor

The N_2O emission factor was used to estimate GHG from hydrogen combustion for the following:

- Infrastructure: Production, Storage, and Transmission
- End-Users: Mobility, Power Generation, and Hard to Electrify Industrial

Production

Electrolysis Powered by Renewable Electricity

The process of electrolysis is not a combustion process and therefore N2O emissions are zero.

Biomass Gasification

No method for calculating greenhouse gas emissions was identified for biomass gasification, nor were any directly measured emissions from the process. Based on the scientific literature, biomass gasification is likely a "carbon neutral" process and may have negative life cycle greenhouse gas emissions.[125] The reason is that growing biomass removes carbon dioxide from the atmosphere. It is assumed for the purposes of this study, that a "carbon neutral" source of biomass will be selected for the production of hydrogen to be distributed by Angeles Link. Therefore, no CO_2 or CH_4 emissions are assumed from the biomass gasification process. Biomass gasification is a controlled process involving heat, steam, and oxygen to convert biomass to hydrogen and other products without combustion, and it occurs at high temperatures greater than 700 degrees Celsius. As such, it was assumed that N_2O formation during biomass gasification is negligible. However, very little scientific literature is available that addresses the potential formation of N_2O from biomass gasification. A study completed by Sikarwar et al. in 2016 notes that there is the potential for nitrogen contamination in the outlet of the biomass gasification system if there is fuel nitrogen is present.[126] For the purposes of this study, it was assumed that no nitrogen is contained in the biomass or any other fuel source, as hydrogen is the preferred fuel source within the Angeles Link supply chain. Therefore, for the purposes of this study, it was assumed that N_2O emissions from biomass gasification were negligible.

[125] Yaser, Khojasteh Salkuyeh, Bradley A. Saville, Heather L. MacLean, International Journal of Hydrogen Energy Volume 43, Issue 20, 17 May 2018, Pages 9514-9528, Techno-economic analysis and life cycle assessment of hydrogen production from different biomass gasification processes https://www.sciencedirect.com/science/article/abs/pii/S0360319918311182

[126] Sikarwar, V.S., M. Zhao, P. Clough, J. Yao, X. Zhong, M. Zaki Memon, N. Shah, E.J. Anthony and P.S. Fennell, 2016, An overview of advances in biomass gasification, Energy and Environmental Science 9(10): 2927-3304, https://pubs.rsc.org/en/content/articlepdf/2016/ee/c6ee00935b

The biomass gasification process requires dry biomass. It is possible to obtain biomass containing moisture that would require drying on-site. However, this is dependent on the biomass available in the area and the supply chain and procurement for the specific facility. Due to the level of uncertainty around whether on-site drying would be required for each specific biomass gasification facility, this study assumed that biomass would be procured ready to utilize and would not require moisture removal on-site.

The syngas formed through biomass gasification can potentially be utilized in steam reforming to obtain additional hydrogen from the remaining hydrocarbons. Biomass gasification using steam as the oxidizing agent can achieve efficiencies of up to 44%.[127] Running the syngas through the steam reforming process improves the overall efficiency and converts any remaining hydrocarbons, primarily CH_4, to hydrogen.

<u>SMR Utilizing RNG as Feedstock and Hydrogen as Fuel for Heat Generation</u>

For the purposes of this study, it was assumed that renewable natural gas generated from dairy farms would be the feedstock for the SMR process. Renewable natural gas, as it is referred to in this study, is a useable feedstock for the SMR process as it generally has a methane content of 96% to 98%.[128] Biomethane is a type of renewable natural gas which is typically developed by the anaerobic digestion of manure and/or food wastes at a dairy farm or similar facility. The anaerobic digestion of these waste products generates a gaseous and a liquid product. The gaseous product is known as biogas and is subsequently sent through a cleaning skid where pollutants and impurities are removed resulting in renewable natural gas. The liquid product is called digestate and may be used as fertilizer in agriculture.

Steam reforming of renewable natural gas does have the potential to produce direct GHG emissions. Potential point sources of direct GHG emissions from combustion within a hypothetical steam reforming process include a furnace or external combustion unit for heat generation and may include a flare for use during maintenance, upset, and startup/shutdown operations. Given that pure hydrogen will be used as fuel for the combustion process, there is no potential for the formation of CO_2 or CH_4 emissions from the combustion hydrogen within the SMR process. However, there is the potential for N_2O formation from the combustion of hydrogen.

To calculate N_2O emissions from the external combustion unit within the steam reforming process, a heat rating per unit of hydrogen produced was required. To estimate an appropriate heat rating for the steam reforming process, air permits for existing steam

[127] Rödl, A., C. Wulf, M. Kaltschmitt, 2018, Chapter 3 – Assessment of Selected Hydrogen Supply Chains—Factors Determining the Overall GHG Emissions in Hydrogen Supply Chains, Editor: C. Azzaro-Pantel, Academic Press, ISBN 9780128111970, https://doi.org/10.1016/B978-0-12-811197-0.00003-8
[128] EPA, 2024b, Renewable Natural Gas, https://www.epa.gov/lmop/renewable-natural-gas

methane reforming plants were reviewed. Only standalone SMR production facilities, external combustion units with a given heat rating rather than a “not-to-exceed", and facilities with no more than 2 external combustion units were reviewed.

The external combustion unit heat rating was compared against the plant hydrogen production capacity to develop a ratio of (MMBtu/hr) / (MMscf/day hydrogen production) ratio. For facilities where the plant hydrogen production capacity was not stated in the air permit, the facility hydrogen production capacity was gathered from the Pacific Northwest National Laboratory (PNNL) Hydrogen Analysis Resource Center North American Merchant Hydrogen Plant Production Capacity list.[129] Of these facilities considered, the highest (MMBtu/hr) / (MMscf/day hydrogen production) ratio was 3.71 MMBtu/hr per MMscf/day hydrogen production, and the average was 2.97 MMBtu/hr per MMscf/day hydrogen production. Three calculation cases were established, the maximum case using the average plus standard deviation for the ratio value (3.62 MMBtu/hr per MMscf/day H2 production), the moderate case using the average ratio value (2.97 MMBtu/hr per MMscf/day H2 production), and the minimum case using the average minus the standard deviation for the ratio value (2.32 MMBtu/hr per MMscf/day H2 production).

For the purposes of this study, it is assumed that the external combustion unit would operate using hydrogen as fuel. It was assumed that some of the hydrogen produced by SMR would be siphoned off to use as fuel. As such, the volume of hydrogen produced was increased based on the amount of hydrogen that would be needed as fuel. To calculate the amount of hydrogen that would be required for use as fuel to generate the necessary total volume of hydrogen to meet end-user demand, the end-user demand was converted to an MMscf/day value and the maximum MMBtu/hr case of 3.62 MMBtu/hr per MMscf/day of hydrogen production was utilized to determine an appropriate MMBtu/hr rating to meet the demand. The MMBtu/hr values were multiplied by 8,760 (hours/year) to calculate the maximum annual MMBtu value for the hydrogen fuel. This annual MMBtu value was added to the end-user MMBtu demand values for each Demand Scenario to determine the total estimated annual production volumes.

A thermal efficiency was then applied to account for the fact that energy conversion is generally less than 100%. Research was completed to determine an appropriate thermal efficiency for a hydrogen fueled external combustion unit. No single value was discovered that would be representative for all hydrogen fueled external combustion units. Therefore, an average of multiple values was utilized. Values were obtained from DOE, a study completed by Gupalo et al. (2023), and an article by Gerardo Lara in Power

[129] Pacific Northwest National Laboratory (PNNL), 2016, North American Merchant Hydrogen Plant Production Capacities, data available on the Hydrogen Tools website, https://h2tools.org/hyarc/hydrogen-data/merchant-hydrogen-plant-capacities-north-america

Engineering.[130] [131] [132] Based on these articles, an efficiency of 73% was applied within this study.

Based on this methodology, roughly 38% of the hydrogen produced would be utilized as fuel for heat generation. As a note, this is likely a high estimate due to the use of only the maximum MMBtu/hr per MMscf/day hydrogen production ratio to determine fuel requirements. Utilizing the average case ratio yields a hydrogen use percent of total production of 31%, where the minimum case ratio yields 24%.

N_2O emissions factors for external combustion were calculated utilizing the same process as outlined for stationary combustion end-users and the conservative value of 2 ppmvd (equivalent to 0.0265 kg CO_2e/kg H_2 combusted) was conservatively utilized for external combustion. The calculations within this study assumed that hydrogen was the fuel for the external combustion unit within the SMR operations.

Storage and Transmission

A two-step calculation approach was utilized to determine N_2O emissions from storage and transmission:

Estimate the total energy requirements to power compressors.

Calculate emissions from reciprocating engines and turbines associated with this energy.

The total energy requirement to power compressors for storage and transmission were developed from Bossel and Eliasson (2003)[133], a widely cited scientific paper. The first figure below, is a chart from this publication of compression energy (MJ/kg) to compress hydrogen at various pressures. Using this figure, the amount of energy required to store hydrogen can be calculated given a particular quantity of hydrogen (kg) and storage pressure (bar). The second chart from this this publication, the second figure below is a chart of the percentage of hydrogen that would be consumed to power compressors to transport hydrogen over a particular distance of pipeline. This figure can be used to calculate the amount of hydrogen (and therefore energy) required to transport hydrogen

a distance via pipeline. Using these two data sources, the total energy required to power compressors used for storage and transmission could be determined.

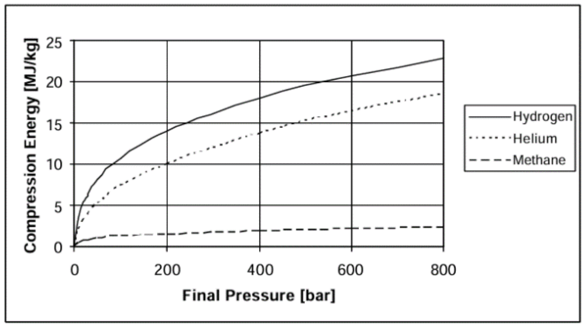

Figure A-1. Adiabatic Compression Work for Hydrogen, Helium, and Methane

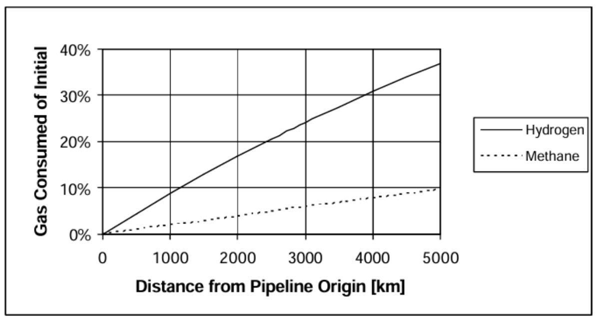

Figure A-2 Fraction of Gas Consumed to Energize the Pumps Corresponds to the Relative Energy Consumption of the Transported Gas

Based on data from Bossel and Eliasson (2003), the following information was required to determine N_2O emissions from transmission and third-party storage:

- Hydrogen storage pressure
- Hydrogen storage quantity
- Hydrogen transmission distance
- N_2O emissions factors for reciprocating engines and turbines

A range of possible N_2O emissions scenarios were evaluated related to new hydrogen infrastructure. A total of four scenarios were evaluated (per Demand Scenario) representing each combination of two (2) storage pressure scenarios, (2) compressor power source scenarios, and one (1) transmission distance scenarios. Annual N_2O emissions estimates were developed for each of these four storage and transmission scenarios for each of the three Demand Scenarios (conservative, moderate, and ambitious).

Storage pressure scenarios were developed based on storage pressures from Tahan (2022).[134] This publication presented a variety of hydrogen storage options at a high-level

[134] Tahan, M., 2022, Recent advances in hydrogen, Ibid

and their corresponding pressures. The highest and lowest pressures from this publication were utilized to represent the full range of potential storage pressures, and therefore storage compressor energy demands, from this project. These high and low storage pressure scenarios were 200 and 20 bar respectively, corresponding to storage underground and in spherical pressure vessels respectively.

A conservative N_2O emissions factor of 2 ppmvd (equivalent to 0.0265 kg CO_2e/kg H_2) was utilized to represent the potential for N_2O formation from the combustion of hydrogen with air. This same factor was used for reciprocating engines and turbines. Efficiency values for reciprocating engines and turbines were also sourced from scientific literature to convert fuel energy (MMBtu) to energy supplied by power sources for compression (MJ). These efficiency values were 60.3% and 51.9% for hydrogen fueled reciprocating engines and turbines respectively.[135] [136] A transmission distance of 450 miles of pipeline was assumed.

It was assumed that storage requirements would be similar between hydrogen and natural gas to accommodate fluctuations in fuel supply and demand. Data from 2022 from the "2023 California Gas Report Supplement" was used to estimate a California-specific value for the fraction of annual hydrogen demand that would be stored. From this source, it was determined that the average quantity of supplied natural gas in California during 2022 was 6,023 MMcf/day, which equates to approximately 2,198 Bcf/yr. This source also indicated that in 2022 California had a natural gas storage capacity of approximately 304 Bcf. Dividing these two values yielded a maximum (conservative) fraction of annual natural gas demand that would be stored: 13.8%. This value was applied to hydrogen; therefore, it was assumed that annually 13.8% of hydrogen demand would be stored.

Collectively, this information was used to determine the energy requirements for the compressors utilized in storage and transmission. N_2O emissions, as CO_2e, from storage and transmission were calculated by multiplying overall compressor energy demand by N_2O emissions factor by N_2O GWP (AR6).

Based on the figures above and information from the literature as summarized above, the compression needs for storage were determined to be 4 MJ/kg for storage pressure at 20 bar and 14 MJ/kg for storage pressure at 200 bar, Additionally, for transmission, the hydrogen that would be consumed by the reciprocating or centrifugal compressors, was

---

[135] Babayev, R., H.G. Im, A. Andersson, and B. Johansson, 2022, Hydrogen double compression-expansion engine (H2DCEE): A sustainable internal combustion engine with 60%+ brake thermal efficiency potential at 45 bar BMEP, Energy Conversion and Management 264: 115698, https://doi.org/10.1016/j.enconman.2022.115698

[136] Salam, Md A., Md. A. Ali Shaikh, and K. Ahmed, 2023, Green hydrogen based power generation prospect for sustainable development of Bangladesh using PEMFC and hydrogen gas turbine, Energy Reports 9: 3406-3416, https://doi.org/10.1016/j.egyr.2023.02.024

determined to be 0.0093% of the volume in the pipelines per kilometer of transmission via pipelines.

The following emission factors were developed for reciprocating engine and turbine compressors combusting clean renewable hydrogen:

- Hydrogen combusted (reciprocating engine & turbine compressors)
    - 2.1673E-11 grams CO_2e per gram H_2
    - 0.0005988 MT CO_2e per MMBtu
- Hydrogen transported (reciprocating engine & turbine compressors)
    - 5.5886E-8 grams CO_2e per gram H_2 per kilometer
    - 2.0228E-15 MT CO_2e per MMBtu H_2 per kilometer
- Hydrogen stored at 290 psi (reciprocating engine compressor)
    - 0.01318 grams CO_2e per gram H_2
- Hydrogen stored at 2,900 psi (reciprocating engine compressor)
    - 0.003765 grams CO_2e per gram H_2
- Hydrogen stored at 290 psi (turbine compressor)
    - 0.01531 grams CO_2e per gram H_2
- Hydrogen stored at 2,900 psi (turbine compressor)
    - 0.004374 grams CO_2e per gram H_2

Collectively, this information was used to determine the energy requirements for the compressors utilized in transmission and storage. NOx emissions were calculated by multiplying overall compressor energy demand by NOx emissions factor. NOx emissions were estimated for a total of 12 scenarios corresponding to 4 storage and transmission scenarios for each of the 3 Demand Scenarios. These 4 transmission and storage scenarios were based on each combination of two storage pressure scenarios, two pressure source scenarios, and one transmission distance scenarios. This was repeated for a total of 12 scenarios for each of the 3 Throughput Scenarios. These emissions scenarios are listed in the table below. In combination, these scenarios represent the range of possible transmission and storage characteristics and the corresponding NOx emissions.

Table A-2 Storage and Transmission Calculation Scenarios Evaluated

Scenario	Storage Pressure	Transmission Distance	Compressor Driver	Demand
1	High (2,900 psi)	450 mi	Reciprocating Engine	Low
2	Low (290 psi)	450 mi	Reciprocating Engine	Low
3	High (2,900 psi)	450 mi	Turbine	Low
4	Low (290 psi)	450 mi	Turbine	Low
5	High (2,900 psi)	450 mi	Reciprocating Engine	Moderate
6	Low (290 psi)	450 mi	Reciprocating Engine	Moderate
7	High (2,900 psi)	450 mi	Turbine	Moderate
8	Low (290 psi)	450 mi	Turbine	Moderate
9	High (2,900 psi)	450 mi	Reciprocating Engine	High
10	Low (290 psi)	450 mi	Reciprocating Engine	High
11	High (2,900 psi)	450 mi	Turbine	High
12	Low (290 psi)	450 mi	Turbine	High

Mobility

The EMFAC model does not include CH_4 and N_2O emissions data for off-road mobile vehicles. As such, additional research was completed to establish the most representative CH_4 and N_2O emissions factors for off-road mobile sources. The EPA Emission Factors for Greenhouse Gas Inventories document most recently modified on September 12, 2023 was selected as the most appropriate and representative source for CH_4 and N_2O emissions factors for off-road mobile sources. The document consolidates these emissions factors from the Annex tables in the EPA (2022) Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2020. Table A-3 is a summary of the GHG emission factors that were developed for the mobility sector. Table A-4 summarizes the allocation of each mobility sub-sector to the two fossil fuels being displaced, diesel and gasoline, as a total for the fifteen-year study period.

Table A-3 GHG Emission Factors by Fuel Type for On-Road & Off-Road Vehicles

Vehicle Type	Fuel Type	CO_2 (MT/gal)	CH_4 (MT/gal)	N_2O (Mt/gal)
On-Road	Diesel	0.0102	2.2078E-08	1.6000E-06
On-Road	Gasoline	0.0086	2.7499E-07	3.2282E-07
Off-Road	Diesel	0.0100	2.1960E-06	7.8800E-07
Off-Road	Gasoline	0.0065	1.7100E-06	1.0560E-06

Table A-4 Percentage of Total Fuel Type Displaced for each Mobility Sub-sector 2030 to 2045

Subsector	BAU % Diesel	BAU % Gasoline
MDV	38.81%	61.19%
HDV	99.99%	0.01%
Bus	10.15%	89.85%
Ag	92.14%	7.86%
CHC	100.00%	0.00%
CHE	27.55%	72.45%
C&M	67.65%	32.35%
GSE	18.28%	81.72%

Power Generation and Hard to Electrify Industrial

The research completed for this study did not reveal any published hydrogen-specific GHG combustion emission factors. There is agreement within scientific literature that the formation of carbon GHGs (CO_2 and CH_4) will be zero from the combustion of hydrogen fuel. Reductions of CO_2 and CH_4 emissions will therefore be 100% when compared to the emissions calculated for the fossil fuels displaced by hydrogen. The combustion of hydrogen at lower temperatures does provide potential for the formation and emissions of N_2O. However, there is uncertainty around the contributing factors to the formation and N_2O emissions. This uncertainty was discussed in the N_2O development of emissions factor section above.

Appendix B: Carbon Intensity Evaluation of Third-Party Production Options

This evaluation sought to gather existing data regarding potential lifecycle GHG emissions associated with electrolysis powered by renewable electricity, biomass gasification, and SMR of RNG using hydrogen as fuel for any combustion units. Lifecycle GHG emissions associated with hydrogen production include direct (Scope 1) and indirect emissions (Scope 2 and Scope 3).

At the time of this study, details regarding third-party production for new hydrogen infrastructure are not complete, and therefore, it is not feasible to estimate Scope 3 greenhouse gas emissions for the specific processes. It is critical to note that none of the lifecycle carbon intensities referenced in this section were developed for Angeles Link, they are all hypothetical scenarios or based on existing facilities and therefore, are not necessarily representative of the third-party production options being evaluated. The carbon intensity values presented in this section were obtained from existing literature and do not represent the full range of potential carbon intensities for each hydrogen production methodology. Based on the assessment within this study and with the information currently available, it is not possible to determine which of the potential hydrogen production methodologies will best meet the CPUC definition for clean renewable hydrogen. However, based on existing data, it appears to be possible for all three of the methodologies being considered to meet the CPUC definition depending on operational variables.

Multiple studies found in the literature were prepared to assess the lifecycle carbon intensity (kg CO_2e/kg H_2 produced) for the various hydrogen production methodologies. While there is not a single standardized methodology and structure for Life Cycle Assessments (LCA), existing standards include International Organization for Standardization (ISO) 14040 and ISO 14044, and assessment methods such as ReCiPe2016.[137] [138] Key variables for assessing carbon intensity for each methodology include the type and amount of feedstock required, type and amount of process fuels required, electricity required, water required for each of the various production methods, and the full supply chain for the required feedstock and fuel. The Greenhouse gases, Regulated Emissions, and Energy use in Transportation (GREET) Model[139] is a publicly available tool that estimates “well-to-gate” (WTG) or “well-to-wheel” carbon intensity for

---

[138] Mehmeti, A., A. Angelis-Dimakis, G. Arampatzis, S.J. McPhail and S. Ulgiati, 2018, Life Cycle Assessment and Water Footprint of Hydrogen Production Methods: From Conventional to Emerging Technologies, Environments 5(2), https://doi.org/10.3390/environments5020024

[139] Argonne National Laboratory, 2022a, GREET Model Detail: The Greenhouse gases, Regulated Emissions, and Energy use in Technologies Model (GREET) | Bioenergy Models | NREL

hundreds of pathways, including hydrogen production, and was also utilized to assess potential life cycle carbon intensities.

For this analysis, an evaluation was conducted to determine the "well-to-gate" carbon intensity for the following hydrogen production methods:

- Electrolysis powered by renewable electricity
- Biomass gasification
- Steam methane reforming (SMR) of feedstock renewable natural gas (biomethane)

Carbon intensity can be presented in multiple ways. For this study, emissions are presented in kilograms of carbon dioxide equivalent per kilograms of hydrogen produced (kg CO_2e/kg H_2) for comparison with the carbon intensity of 4 kg CO_2e/kg H_2 which is part of the CPUC definition of clean renewable hydrogen. The table below presents a summary of life cycle carbon intensities for the various production methodologies from existing literature which are discussed in more detail in the sections below.

Table B-1 Summary of Hydrogen Production Carbon Intensity Estimates from Existing Research

Production	Feedstock	Carbon Intensity Cradle-to-Gate (kg CO_2e/kg H2)	Study
Electrolysis	Renewable Electricity	0	GREET
Electrolysis	Solar-powered Electricity	2.3	Cho et al. 2022
Biomass Gasification	Not Specified	1.61	GREET
Biomass Gasification	Average of five biomass types	2.46	Cho et al. 2022
Steam Methane Reforming	Landfill Gas	3.57	Cho et al. 2022

<u>Electrolysis Powered by Renewable Electricity</u>

Per the GREET model, GHG emissions associated with electrolysis powered by renewable electricity are zero. GREET does not account for embedded carbon associated with solar panels or wind turbines. A study by Cho et al. published in 2022 found that solar-powered electrolysis may have a carbon intensity of 2.3 kg CO_2e/kg H_2 largely due to the manufacture of the solar cells.[140] As demonstrated, carbon intensity for electrolysis powered by renewable electricity will vary based on how the required technology is manufactured, even when Scope 1 and Scope 2 emissions are zero.

[140] Cho, H.H. et al. 2022, Environmental impact assessments, Ibid

Research has also noted that electrolysis requires high quality water as a feedstock, which may require treatment on site potentially increasing the energy demand[141] and impact overall carbon intensity.

Biomass Gasification

In the direct GHG emission calculations, we assume that biomass gasification is a "carbon neutral" process. Assuming no grid electricity usage or natural gas combustion, GREET was used to calculate indirect GHG emissions associated with biogas gasification, assuming that 36.3 kg of biomass is needed to produce 1 kg H_2.[142] Approximately 1.61 kg CO_2e/kg H_2 is emitted by Scope 3 indirect sources (cultivation, harvesting, transport, drying, and chipping) for the biomass gasification process. Cho et. al (2022) calculated a cradle-to-gate carbon intensity of 2.46 kg CO_2e/kg H_2 for biomass gasification as an average of carbon intensity values from six different studies encompassing the following types of biomass: corn stover, unspecified forest residue, poplar, spruce, and willow.[143]

The carbon intensity of biomass gasification can vary based on a variety of key inputs including, but not limited to, type of biomass feedstock, whether fossil energy is used in the biomass lifecycle, biomass transport, pre-treatment such as drying and chipping, and the use of synthetic fertilizers. Fossil energy may be used in the agricultural process such as diesel fuel in agricultural machinery and vehicles. The use of synthetic fertilizers during the biomass lifecycle can cause acidification which can impact the carbon intensity of that biomass.[144]

Steam Methane Reforming

In the SMR process, hydrogen is produced through a reaction of gaseous methane and steam to produce a carbon monoxide (CO) – hydrogen synthetic gas (syngas). The CO in the syngas is then further reacted with steam to produce CO_2 and additional hydrogen. Note that if the steam is exported for other uses, a process credit may be calculated, assuming emissions avoidance from a natural gas boiler that would have produced an equal amount of steam. SMR being considered would use renewable natural gas as feedstock. The direct emissions calculations completed within this study assume that the produced hydrogen is utilized as fuel for heat generation in the SMR process. However, no studies were identified that assume the use of hydrogen as fuel.

Cho et al. evaluated cradle-to-gate carbon intensity for utilizing landfill gas as feedstock for the SMR process. They took an average of the carbon intensities from three landfill gas related studies, one of which specified an assumed leakage rate of 1% CH_4, while the other two did not specify leakage rate assumptions. The cradle-to-gate carbon intensity for SMR of landfill gas was estimated to be 3.57 kg CO_2e/kg H_2.[145] The value presented in this section may not appropriately represent SMR utilizing renewable natural gas as

[141] Mehmeti, A.et al. 2018, Life Cycle Assessment, Ibid
[142] Argonne National Laboratory, 2022b, Hydrogen Life-Cycle Analysis, Ibid
[143] Cho, H.H. et al. 2022, Environmental impact assessments, Ibid
[144] Cho, H.H. et al. 2022, Environmental impact assessments, Ibid
[145] Cho, H.H. et al. 2022, Environmental impact assessments, Ibid

feedstock since the renewable natural gas is typically derived from dairy farms rather than landfills. The average carbon intensity for manure dairy farms is considerably lower than landfill gas estimates found in the study, 3.57 kg CO2e/kg H_2. The CI for manure dairy farms on average is several orders of magnitude lower at approximately –322 kg CO2e/kg H_2.[146]

Production efficiency is a highly impactful variable when determining lifecycle carbon intensity from any SMR process. Cho et al. (2022) found that direct carbon intensity from SMR (using natural gas as feedstock) decreased by 6% when the efficiency was increased by 5% and decreased by 11% when the efficiency was increased by 10%.[147] A study by Nikolaidis and Poullikkas published in 2017 noted that the average production efficiency for existing SMR facilities ranges from 74% to 85%. Increasing the production efficiency of an SMR process reduces the carbon intensity.[148]

	This tab includes the acronym PRJ. This refers to the project (PRJ) scenario used in the calculation process (particularly for stationary sources). The PRJ scenario encompasses emissions for a sector or subsector including hydrogen adoption. For end-users, the PRJ scenarios are sector-wide representations of emissions, therefore PRJ scenario emissions will encompass emissions from sources that switched to hydrogen or blended fuels and emissions from sources that remained combusting fossil fuels. For stationary sources (industrial and power), PRJ scenarios were used to develop change in emissions results by subtracting the baseline from the project scenario emissions. For mobility, change in emissions were developed without considering a PRJ scenario, but this information was still developed and included for consistency within the end-user results. The key findings reported in this study were change in emissions (due to hydrogen adoption either at a market level or as supplied by Angeles Link). While PRJ scenario information was used to develop certain results, this information is secondary to the core results of this study.

2	**Tab Contents**									
4	This tab includes the acronym PRJ. This refers to the project (PRJ) scenario used in the calculation process (particularly for stationary sources). The PRJ scenario encompasses emissions for a sector or subsector including hydrogen adoption. For end-users, the PRJ scenarios are sector-wide representations of emissions, therefore PRJ scenario emissions will encompass emissions from sources that switched to hydrogen or blended fuels and emissions from sources that remained combusting fossil fuels. For stationary sources (industrial and power), PRJ scenarios were used to develop change in emissions results by subtracting the baseline from the project scenario emissions. For mobility, change in emissions were developed without considering a PRJ scenario, but this information was still developed and included for consistency within the end-user results. The key findings reported in this study were change in emissions (due to hydrogen adoption either at a market level or as supplied by Angeles Link). While PRJ scenario information was used to develop certain results, this information is secondary to the core results of this study.

Tab Contents

Summary of production GHG emissions results and minor calculations to develop results. The Demand Scenario results include emissions from hydrogen produced, stored, and transmitted by third-parties, in addition that hydrogen associated with Angeles Link. The Angeles Link results are specific to the hydrogen produced, stored, and transmitted within the Angeles Link system.

Market Scenario - Production - GHG

Note: raw data was copied from "ALP1_GHG_Prod_1_Calcs_SoCalGas.xlsx", tab "1. Prod_N2O_Summary".

Tab Contents

Summary of infrastructure GHG emissions results and minor calculations to develop results. The Demand Scenario results include emissions from hydrogen produced, stored, and transmitted by third-parties, in addition that hydrogen associated with Angeles Link. The Angeles Link results are specific to the hydrogen produced, stored, and transmitted within the Angeles Link system.

This tab includes the acronym PRJ. This refers to the project (PRJ) scenarios used in the calculation process (particularly for stationary sources). The PRJ scenario encompasses emissions for a sector or subsector including hydrogen adoption. Since infrastructure would only be present in the PRJ scenario, and therefore emissions would only occur in the PRJ scenario. The key findings reported in this study were change in emissions (due to hydrogen adoption either at a market level or as supplied by Angeles Link). While PRJ scenario information was used to develop certain results, this information is secondary to the core results of this study.

Market Scenario - Storage - GHG

Note: raw data was copied from "ALP1_GHG_S&T_2_CalcTool_SoCalGas.xlsx", tab "4.2.2 GHG_Results_Storage".

Tab Contents

Summary of storage and transmission GHG emissions results and minor calculations to develop results. The Demand Scenario results include emissions from hydrogen produced, stored, and transmitted by third-parties, in addition that hydrogen associated with Angeles Link. The Angeles Link results are specific to the hydrogen produced, stored, and transmitted within the Angeles Link system.

This tab includes the acronym PRJ. This refers to the project (PRJ) scenarios used in the calculation process (particularly for stationary sources). The PRJ scenario encompasses emissions for a sector or subsector including hydrogen adoption. Since infrastructure would only be present in the PRJ scenario, and therefore emissions would only occur in the PRJ scenario. The key findings reported in this study were change in emissions (due to hydrogen adoption either at a market level or as supplied by Angeles Link). While PRJ scenario information was used to develop certain results, this information is secondary to the core results of this study.

Market Scenario - Storage and Transmission - GHG

Note: raw data was copied from "ALP1_GHG_S&T_2_CalcTool_SoCalGas.xlsx", tab "4.2 GHG Results".

2		**Tab Contents**						
3		This tab outlines the weighted pollutant emission factors developed for each subsector, year, and fuel type from the EMFAC data. Background data and weighting is occuring on the tabs titled, "Onroad_GHG_day" and "Offroad_GHG_day" except for Offroad CH4 and N2O emission factors. Offoad CH4 and N2O emission factors are pulling from tab "OffRoadCH4N2O".						
4

Tab Contents

This tab calculates the volume of gasoline and diesel fuels displaced specifically by Angeles Link based on the percentages provided by the Demand Study as represented on the tab titled, "AL_Volumes". It also demonstrates the volume of gasoline and diesel displaced by market adoption of FCEVs, as provided by the Demand Study. Emission reductions were calculated by multiplying the displaced fuel volume by the emissions factor.

				Market Displaced Volumes (gal)					
				Diesel	Diesel	Diesel	Gasoline	Gasoline	Gasoline

3					This tab calculates the volume of gasoline and diesel fuels displaced specifically by Angeles Link based on the percentages provided by the Demand Study as represented on the tab titled, "AL_Volumes". It also demonstrates the volume of gasoline and diesel displaced by market adoption of FCEVs, as provided by the Demand Study. Emission reductions were calculated by multiplying the displaced fuel volume by the emissions factor.

Tab Contents

This tab calculates the volume of gasoline and diesel fuels displaced specifically by Angeles Link based on the percentages provided by the Demand Study as represented on the tab titled, "AL_Volumes". It also demonstrates the volume of gasoline and diesel displaced by market adoption of FCEVs, as provided by the Demand Study. Emission reductions were calculated by multiplying the displaced fuel volume by the emissions factor.

Tab Contents

This tab calculates the volume of gasoline and diesel fuels displaced specifically by Angeles Link based on the percentages provided by the Demand Study as represented on the tab titled, "AL_Volumes". It also demonstrates the volume of gasoline and diesel displaced by market adoption of FCEVs, as provided by the Demand Study. Emission reductions were calculated by multiplying the displaced fuel volume by the emissions factor.

Appendix C.3:

Power Generation

GHG Results, Calculations, and Data

	A	C	D	E	F
1					
2	**Tab Contents**				
3	This workbook contains select tabs (including this one) from a proprietary Stantec calculation tool. This data is copied from "ALP1_GHG_IndustPow_3_DataPrep_SoCalGas", "2. Data_Prep_Power" tab. The input data in this tab was processed through the function in "3.1 EQ Power GHG Calc" to produce the results in "4. Calculations".				
4	In this workbook, the terms "Low", "Mid", and "High" correspond to the "Conservative", "Moderate", and "Ambitious" market scenarios.

2	**Tab Contents**				
3	This workbook contains select tabs (including this one) from a proprietary Stantec calculation tool. This data is copied from "ALP1_GHG_IndustPow_3_DataPrep_SoCalGas", "2. Data_Prep_Power" tab. The input data in this tab was processed through the function in "3.1 EQ Power GHG Calc" to produce the results in "4. Calculations".				
4	In this workbook, the terms "Low", "Mid", and "High" correspond to the "Conservative", "Moderate", and "Ambitious" market scenarios.

2	**Tab Contents**				
3	This workbook contains select tabs (including this one) from a proprietary Stantec calculation tool. This data is copied from "ALP1_GHG_IndustPow_3_DataPrep_SoCalGas", "2. Data_Prep_Power" tab. The input data in this tab was processed through the function in "3.1 EQ Power GHG Calc" to produce the results in "4. Calculations".				
4	In this workbook, the terms "Low", "Mid", and "High" correspond to the "Conservative", "Moderate", and "Ambitious" market scenarios.

PRJ Blend-H2 Demand	3,141,898.06	MMBtu/yr	ALP1_GHG_IndustPow_3_DataPrep_SoCalGas.xlsx, 1. Data_Prep_Industrial, Cell AV1349
Blend % H2	26.58	scf/100-scf	ALP1_GHG_IndustPow_3_DataPrep_SoCalGas.xlsx, 1. Data_Prep_Industrial, Cell AV1350
Blend % NG	73.42	scf/100-scf	NG makeup based on % H2 selection
Blend % H2 (Mass)	4.46	lb/100-lb	Percentage of H2 in blend by mass. (%-vol H2 * density-H2) / (%-vol NG * density-NG + %-vol H2 * density-H2)
Blend % NG (Mass)	95.54	lb/100-lb	Percentage of NG in blend by mass. (%-vol NG * density-NG) / (%-vol NG * density-NG + %-vol H2 * density-H2)
Blend % H2 (Heat)	10.80	Btu/100-Btu	Percentage of H2 in blend by heat content. (%-vol H2 * HHV-scf-H2) / (%-vol NG * HHV-scf-NG + %-vol H2 * HHV-scf-H2)

Sample Emission Calculation

5-SoCal_PowerPeakerBaseload (MidModerate_ECGeneral) 2035_H2-NG

10/15/2024

Parameter	Value	Units	Resource
Blend % NG (Heat)	89.20	Btu/100-Btu	Percentage of NG in blend by heat content. (%-vol NG * HHV-scf-NG) / (%-vol NG * HHV-scf-NG + %-vol H2 * HHV-scf-H2)
Blending Check Factor	1,472,873.96	MMBtu/yr	Check factor for blending. This is the PRJ MMBtu of blended natural gas, given default (user input) blending assumptions. If this value exceeds overall PRJ natural gas demand, secondary blending assumptions must be made to satisfy energy balance. Based on the following assumptions: "Blend % H2" = Volume_{Blended-H2} /(Volume_{Blended-H2} + Volume_{Blended-NG}) Volume_{Blended-H2} = MMBtu_{Blended-H2} * 10^6 (Btu/MMBtu) /HHV_{Blended-H2} (Btu/scf) Volume_{Blended-NG} = MMBtu_{Blended-NG} * 10^6 (Btu/MMBtu) /HHV_{Blended-NG} (Btu/scf) The above equations can be used to solve for MMBtu_{Blended-NG} in terms of MMBtu_{Blended-H2}. This value can be compared to overall MMBtu of PRJ natural gas.

Blend % NG (Mass)	95.54	lb/100-lb	Percentage of NG in blend by mass. (%-vol NG * density-NG) / (%-vol NG * density-NG + %-vol H2 * density-H2)
Blend % H2 (Heat)	10.80	Btu/100-Btu	Percentage of H2 in blend by heat content. (%-vol H2 * HHV-scf-H2) / (%-vol NG * HHV-scf-NG + %-vol H2 * HHV-scf-H2)

Sample Emission Calculation

6-SoCal_PowerPeakerBaseload (MidModerate_ECOvens) 2035_H2-NG

10/15/2024

Parameter	Value	Units	Resource
Blend % NG (Heat)	89.20	Btu/100-Btu	Percentage of NG in blend by heat content. (%-vol NG * HHV-scf-NG) / (%-vol NG * HHV-scf-NG + %-vol H2 * HHV-scf-H2)
Blending Check Factor	0.00	MMBtu/yr	Check factor for blending. This is the PRJ MMBtu of blended natural gas, given default (user input) blending assumptions. If this value exceeds overall PRJ natural gas demand, secondary blending assumptions must be made to satisfy energy balance. Based on the following assumptions: "Blend % H2" = Volume_{Blended-H2} /(Volume_{Blended-H2} + Volume_{Blended-NG}) Volume_{Blended-H2} = MMBtu_{Blended-H2} * 10^6 (Btu/MMBtu) /HHV_{Blended-H2} (Btu/scf) Volume_{Blended-NG} = MMBtu_{Blended-NG} * 10^6 (Btu/MMBtu) /HHV_{Blended-NG} (Btu/scf) The above equations can be used to solve for MMBtu_{Blended-NG} in terms of MMBtu_{Blended-H2}. This value can be compared to overall MMBtu of PRJ natural gas.

Blend % H2 (Heat)	6.41	Btu/100-Btu	Percentage of H2 in blend by heat content. (%-vol H2 * HHV-scf-H2) / (%-vol NG * HHV-scf-NG + %-vol H2 * HHV-scf-H2)

Sample Emission Calculation

19-SoCal_PowerCogeneration (MidModerate_ICEngines) 2035_H2-NG

10/15/2024

Parameter	Value	Units	Resource
Blend % NG (Heat)	93.59	Btu/100-Btu	Percentage of NG in blend by heat content. (%-vol NG * HHV-scf-NG) / (%-vol NG * HHV-scf-NG + %-vol H2 * HHV-scf-H2)
Blending Check Factor	11,328.97	MMBtu/yr	Check factor for blending. This is the PRJ MMBtu of blended natural gas, given default (user input) blending assumptions. If this value exceeds overall PRJ natural gas demand, secondary blending assumptions must be made to satisfy energy balance. Based on the following assumptions: "Blend % H2" = Volume_{Blended-H2} /(Volume_{Blended-H2} + Volume_{Blended-NG}) Volume_{Blended-H2} = MMBtu_{Blended-H2} * 10^6 (Btu/MMBtu) /HHV_{Blended-H2} (Btu/scf) Volume_{Blended-NG} = MMBtu_{Blended-NG} * 10^6 (Btu/MMBtu) /HHV_{Blended-NG} (Btu/scf) The above equations can be used to solve for MMBtu_{Blended-NG} in terms of MMBtu_{Blended-H2}. This value can be compared to overall MMBtu of PRJ natural gas.

Parameter	Value	Units	Resource
Blend % NG (Heat)	93.59	Btu/100-Btu	Percentage of NG in blend by heat content. (%-vol NG * HHV-scf-NG) / (%-vol NG * HHV-scf-NG + %-vol H2 * HHV-scf-H2)
Blending Check Factor	6,946,134.13	MMBtu/yr	Check factor for blending. This is the PRJ MMBtu of blended natural gas, given default (user input) blending assumptions. If this value exceeds overall PRJ natural gas demand, secondary blending assumptions must be made to satisfy energy balance. Based on the following assumptions: "Blend % H2" = Volume_{Blended-H2} /(Volume_{Blended-H2} + Volume_{Blended-NG}) Volume_{Blended-H2} = MMBtu_{Blended-H2} * 10^6 (Btu/MMBtu) /HHV_{Blended-H2} (Btu/scf) Volume_{Blended-NG} = MMBtu_{Blended-NG} * 10^6 (Btu/MMBtu) /HHV_{Blended-NG} (Btu/scf) The above equations can be used to solve for MMBtu_{Blended-NG} in terms of MMBtu_{Blended-H2}. This value can be compared to overall MMBtu of PRJ natural gas.
